Busy

with a great big

capital

Telephone lines are humming as they never have hummed before.

About 1,300,000 new telephones have been installed in the past year. An average of 85,000,000 calls are completed every day. Both are all-time records.

The job is big and getting bigger but we're working at top speed to keep pace with every need. And increasing our facilities as fast as possible.

The Bell System put about 400 million dollars into new construction in 1941 and will spend millions more this year.

THE SLOWER-BURNING CIGARETTE MEANS LESS NICOTINE IN THE SMOKE!

MOST physicians concede that the leading constituent of cigarette smoke from a physiologic standpoint is *nicotine*.

Medical—research authorities* find that the slower-burning cigarette produces less nicotine in the smoke. Camel's scientific tests** show that Camels burn slower and that the smoke of Camels contains less nicotine than the average of the other brands tested.

When suggesting a program to improve a patient's smoking hygiene, you may find it of value to recommend Camel, the slower-burning cigarette.

Camel offers a double advantage: Besides the reduction of nicotine intake (and all that this implies in the lessening of physiologic irritation), Camel gives more assurance of your patients' cooperation. Camel's slower-burning, costlier tobaccos maintain *the essential "pleasure factor" in smoking*.

PYREX VOLUMETRIC WARE HAS A BRAND

Control Laboratory ALL ITS OWN

In addition to its general Research Laboratories, Corning also maintains a specialized Volumetric Control Laboratory.

Here skilled technicians maintain the accuracy of all calibrating instruments, check and double check calibrations on all catalog items and supervise the marking of volumetric ware made special to order.

All volumetric standards are in accordance with U.S. Bureau of Standards' recommendations. Standard "Pyrex" Volumetric Ware is held within twice the tolerance, while Corning Certified "Pyrex" Ware is held to within the tolerances and specifications prescribed by the Bureau.

"Pyrex" Pipettes will withstand repeated sterilization (wet or dry). They are affected neither chemically nor thermally by any of the common sterilization methods. Walls are of proper thickness for maximum mechanical strength and convenient handling.

All "Pyrex" Volumetric Ware in Catalog LP21 is available through your regular source of supply.

During the Sun-poor Months This Milk IS NEEDED MORE

**Everybody is a
"SHUT-IN" NOW
in so far as Sun's
Vitamin D is concerned**

The nutritional value of Milk has long been recognized as one of the certainties of medical knowledge and its enrichment with Vitamin D is an important prophylactic measure designed to help abolish Vitamin D deficiencies automatically, economically and on a communal scale.

With sunlight's Vitamin D value at only $\frac{3}{8}$ to $\frac{1}{8}$ of its summer time strength, the months of September to March give special significance to Vitamin D Milk. And we hope you will remind mothers ...this milk gives their children every nutritional advantage of ordinary milk

plus Vitamin D, the essential catalyst that helps to turn calcium and phosphorus into strong, hard, properly formed bones and teeth.

Foundation-licensed dairies offer daily-at-the-door delivery of Vitamin D Milk, enriched with the "sunshine" vitamin by one of three processes. These are: *Irradiation*, *Fortification*, and *Metabolization*. Many dairies further enhance the flavor and nutritive values of these milks by homogenization or the SoftKurd process.

If your practice is located in a "Vitamin D Milk Community", why not say "and be sure your family gets plenty of *Vitamin D Milk*."

All Foundation-licensed dairies are entitled to use this Seal on their Vitamin D Milk and in related ad-

vertising. All such milks are tested periodically by the Foundation whether or not the Seal appears thereon.

ON YOUR DOORSTEP

Two "Ifs" ... and an Important "BUT" ... for the Harried Health Officer

IF chemical solutions were always kept effective and immersion periods always checked . . . and **IF** dish-water temperatures were never allowed to cool below the safety point . . . then the Inspector's task of sanitation supervision would be much easier.

BUT rush-hour haste all too often results in neglected glass-washing . . . and that means increased danger of mouth-to-mouth contagion.

Single-service Dixie Cups are the sensible answer.

For Dixies require no sanitizing whatever — they are used just once, and then discarded. They provide each customer with individual health-protection.

Small wonder, then, that over-worked Health Officers everywhere are always glad to see Dixie Cups installed at soda fountains. For Dixies really lighten the burden on any Sanitarian.

DIXIE and VORTEX CUPS for America's Health Defense are made at Easton, Pa., Chicago, Ill., Darlington, S. C., and Toronto, Can.

"We're backing them up"

Marching right along with the armed forces of this country are thousands of telephone workers.

They work side by side with the Army and Navy. Wherever the need is communications, you are likely to find telephone men and their trucks and materials.

Day and night the order is for speed and more speed.

They wear no uniforms, these telephone workers, but men in uniform know how much they are putting into the Nation's biggest job. They see it first-hand and they know it is first-rate.

A New Efficient Sanitizing Agent

A cationic detergent of high germicidal potency

ROCCAL is an entirely new type of germicide developed on a totally different chemical basis—a 10% aqueous mixture of high molecular alkyl-dimethylbenzyl-ammonium chlorides.

More than 100 public health departments have approved and will allow the use of ROCCAL as a sanitizing agent for public eating and drinking utensils.

A test kit is available

• **Bactericidal potency.** ROCCAL is capable of reducing the bacteria count on public eating and drinking utensils to levels far below those of health department requirements.

• **Rapidity of action.** ROCCAL destroys Staph. aureus in less than one second, compensating for universal habit of short cut sanitizing.

• **Non-Irritating to operators' hands.** Thousands have used it without bad effects. It is emollient, soothing.

• **Economy.** ROCCAL is not expensive, potency and stability considered.

• **Stable, Non-Volatile.** ROCCAL maintains its potency regardless of temperature levels.

• **Odorless and Virtually Tasteless.**

• **Non-Toxic, Non-Poisonous, Non-Corrosive.**

A Helping Hand for Short-handed Health Departments

WITH the new emphasis on public health as a crucial influence on our national war effort, overworked health officials face a real problem . . . particularly in areas around vital defense industries. Even if Health Department budgets provided larger staffs, supervising soda fountain sanitation would be difficult enough.

For the best-intentioned fountain operator will admit that rush-hour business sometimes results in careless glass-washing. Chemical solutions become too weak to be effective, and dish-water temperatures are frequently neglected. And the supervising task of the already harried Sanitarian becomes that much harder.

But single-service Dixie Cups offer a helping-hand to short-handed Health Departments everywhere. Mouth-to-mouth contagion is avoided, when every customer is served in an individual Dixie Cup. For a Dixie Cup is used just once, then thrown away.

With Dixie on the job, the task of the inspector is greatly simplified.

Dixie and Vortex Cups for America's Health Defense are made at Easton, Pa., Chicago, Ill., Darlington, S. C., and Toronto, Can.

Essential to Maximum
War Effort**

Because physical and mental energy is measured largely in terms of hemoglobin levels, war-time production can be speeded up by Copper-Iron therapy.

The period of recovery for blood donors is greatly shortened. Women taking over Selectees' jobs can be kept at high working efficiency. Mothers in the auxiliary services are better fitted for their expanded duties.

Important to each individual, the gain to the nation can be tremendous—in increased output of work, in higher morale, in greater fitness for difficult days ahead.

Prescribing Copper-Iron Compounds is the quickest and surest route to increasing and maintaining hemoglobin levels.

Copper Plus Iron Brings Faster, Higher Response

Because Copper is needed to catalyze Iron for hemoglobin regeneration, these two elements are always combined in Foundation licensed and approved Copper-Iron Products. Clinical studies have consistently shown the superiority of these compounds over Iron alone in all types of nutritional and secondary anemias.

The booklets shown below present the evidence upon which preference for Copper-Iron Compounds can be soundly based. Write for them today.

This Seal or mention of the Foundation's name is your assurance that the licensed Copper-Iron product is approved by periodic tests.

Will this be another "Measles Year"?

IMMUNE GLOBULIN (Human)

Lederle

THERE IS MOUNTING EVIDENCE that immune globulin modifies measles in children exposed to the disease. Complications are less likely to develop and the patient benefits by the lasting immunity which usually follows the modified infection.

In a recent clinical study, BASMAN* gave "Immune Globulin (Human) Lederle" to 64 children who were exposed to measles and compared the results with those of a control group of 60 children of comparable age. It was used chiefly to modify the attack rather than to prevent the disease. Twelve per cent did not develop measles, 78% had a modified form and 10% developed severe measles.

No complications occurred in the group receiving the human immune globulin; the temperature was lower and the illness of shorter duration. Reactions following intramuscular injection were mild in nature. In the control group there were numerous complications and one death.

"Immune Globulin (Human) Lederle" is easily available, economical and effective in a high percentage of cases.

*BASMAN, J.: West Virginia Med. J., 57:491 (Nov.) 1941.

The FULFILLED PROMISE of a QUARTER-CENTURY AGO STRENGTHENS the PLEDGE of TODAY

IN the face of a great emergency a quarter-century ago, it was necessary to create a new industry in America—the manufacture of high grade laboratory and pharmaceutical glassware.

The Kimble Glass Company is proud indeed of its achievement in meeting demands during that emergency. It is equally proud of its fulfillment of a pledge made to science and industry at that time, a pledge to design and produce, by American labor, laboratory and pharmaceutical glassware to equal or surpass the products of Europe.

Now we are again in a great emergency. Glass products such as Kimble's are urgently needed by Army and Navy medical units, by public health services, by the skilled professions which safeguard the whole American people, fighting under arms or serving at home. Apparatus is needed in industrial laboratories where strategy and tactics are worked out to win the Battle of Production. The demands are vastly more complicated and extensive now than twenty-five years ago.

Today the Kimble organization renews its pledge, and is devoting every facility to meet the demands for material so important to ultimate victory.

THIS *Seal* IS OUR PLEDGE TO YOU

For more than 15 years, laboratory and clinical research have been employed by the Wisconsin Alumni Research Foundation to prove its steps scientifically, and to justify your complete confidence.

More than 60,000 pages of laboratory records on 200,000 rats record the bioassays, conducted to U.S.P. standards, that continually check and recheck the Vitamin D potency of all products licensed by the Foundation.

Add also the knowledge gained through independent clinical studies on more than 3,500 children to determine the antirachitic values of licensed Vitamin D products.

The Foundation Seal—or the imprinted name of the Foundation itself—is our pledge to you that all products so identified can be accepted with fullest confidence as dependable sources of Vitamin D—tested regularly for standard potency.

ABOUT THE FOUNDATION—The Wisconsin Alumni Research Foundation was established in 1925, not for private profit. It receives and administers patentable discoveries, voluntarily assigned. Through licensing arrangements with reliable companies funds are obtained. All net avails are devoted to further research. Foundation Trustees serve without pay. A booklet, "Scholars From Dollars," tells about the Foundation and its activities. It will be sent at your request.

YOU ARE PRACTICING WAR TIME

ECONOMY

When You Standardize on

PYREX^{BRAND} TEST TUBES

Today, more than ever before, every laboratory—in the schools, in the colleges, in hospitals or industry—is vitally interested in conserving and prolonging the life of its laboratory ware.

This war time economy extends even to the most common of all laboratory apparatus—the every-day test tubes. The longer life of "Pyrex" test tubes comes from the Balanced Glass of which they are made—mechanically, thermally and chemically *balanced*; uniform wall thickness; well rounded bottoms with even glass distribution; well tooled rims; and careful annealing in specially constructed temperature controlled lehrs.

There's no guesswork in purchasing "Pyrex" test tubes. Laboratories maintaining accurate records of purchases and replacements have proven to their own satisfaction that "Pyrex" test tubes offer most in longer life, greater convenience, safety and economy. Figure test tube costs not by the dozen—but by the year.

Your laboratory supply dealer can supply you. Consult Catalog LP21 for complete information.

The Newer Concepts of Meat in Nutrition

Meat . . .

and the Dietary of Elderly Persons

IN VIEW of the ever-lengthening span of life in the United States, the dietary problems of senescence assume a position of importance, not only for the maintenance of vigor and sound health, but also in the prevention and treatment of disease processes characteristic of senility.

Depressed gastric secretion and the digestive disturbances which in many instances are associated with senescence, plus the elderly person's voluntary (and usually indiscriminate) dietary restrictions, not infrequently produce a real nutritional deficiency during advanced years. A nutritionally adequate diet is essential in old age, and ample amounts of proteins, vitamins and minerals are necessary components of such a diet.

Elderly persons require just as much protein per pound of body weight as other, younger adults. Unless sufficient protein-rich foods are consumed, the body cannot be maintained in nitrogen equilibrium. Touhy¹ points out that it is practically impossible to keep down weight and avoid overtaxing carbohy-

drate tolerance, unless the dietary of elderly persons provides an adequate amount of proteins. Meat proteins, high in biologic value, are readily converted to the body's needs, and are promptly utilized.

In addition, meat is a rich natural source of the essential B vitamins—thiamine, riboflavin, nicotinic acid, pantothenic acid, and probably other members of the B complex—all of which are involved in the intricate mechanism of cellular respiration.

Because of the marked decrease in salivary ptyalin and pancreatic amylase occurring between 60 and 80 years of age, a high-starch diet, frequently preferred by the elderly because it is easy to chew, may be harmful.² Meat stimulates the secretion of digestive juices,³ thus sharpens the appetite, and improves digestion in general.

KIMBLE'S NEUTRAGLAS (N-51A GLASS)

.. NOW AVAILABLE IN MOLDED CONTAINERS ..

Clinically Safe!

The fact that glass is soluble is frequently overlooked. But in connection with pharmaceutical and biological products the effect on quality, potency, and the change in pH can be serious.

Kimble's NEUTRAGLAS (N-51A Glass), being neutral in character, resists solvent and chemical attack. It is recognized as **CLINICALLY SAFE**, even for indefinite storage of sensitive products.

Be Calm Courteous Effective

Right now, when times are tense and everybody is under strain. "The Voice with a Smile" is more important than ever.

We've all got a big job to do and the friendly, effective use of the telephone helps every one do it faster and better.

The calm way is usually the competent way. Being courteous usually means saving time and tempers all along the line.

WHOOPING COUGH VACCINE

Squibb

*... prepared by method of Kendrick and Eldering
... tested for antigenicity before release for sale*

ATTESTING to the already well-recognized efficacy of the Kendrick and Eldering pertussis vaccine is a report¹ of an extensive study conducted in Binghamton, N. Y., from January 1, 1939 to November 1, 1940. The vaccinated group consisted of 587 children from six months through four years of age, while 699 children of the same age range formed the control group.

A summary of the study states: "During the period of observation, the pertussis attack rate was more than twice as high in the control group as in the vaccinated group and the cases of pertussis which did occur among the vaccinated group were distinctly less severe than those which occurred among the control children... Reactions to the vaccine were negligible."

Whooping Cough Vaccine Squibb is prepared in exact accordance with the method of Kendrick and Eldering. An average of six cultures are used, all of which have been freshly isolated from cases of whooping cough within three months. The organisms are carefully examined for phase I characteristics and each lot of vaccine is tested for its antigenicity before release for sale.

Whooping Cough Vaccine Squibb (Biologic No. 14) is distributed in 8-cc. and in 24-cc. vials containing 10,000 million bacilli per 1 cc.

JUST 3 SIMPLE STEPS INVOLVED IN CLINITEST THE NEW TABLET URINE-SUGAR TEST

1

5 Drops Urine
plus
10 Drops Water

2

Drop in Tablet

3

Compare with
Color Scale

That is all . . .

TIME—Less Than One Minute!

DEPENDABLE—The CLINITEST Tablet Method employs a modification of Benedict's copper reduction method, retaining the familiar progression of colors from blue through green to orange, indicating sugar at 0%, $\frac{1}{4}\%$, $\frac{1}{2}\%$, $\frac{3}{4}\%$, 1% and 2% plus.

ECONOMICAL—Complete set (with tablets for 50 tests) costs your patient only \$1.25. Tablet Refill (for 75 tests)—\$1.25.

Write for full descriptive literature.

CLINITEST Urine-Sugar Test and CLINITEST Tablet Refill are available through your prescription pharmacy.

Clear the Lines for the War

Before you make a Long Distance telephone call today, ask yourself these questions:

1. Is it necessary?
2. Will it interfere with war calls?

The weight of war on the telephone lines is heavier every day. We can't build the new lines to carry it because sufficient materials aren't available. We've got to make the most of the service we now have.

Please give a clear track to the war effort by confining your Long Distance calls to those that are really necessary.

The Newer Concepts of Meat in Nutrition

Meat and the Non-Allergenic Diet

ABSORPTION of the intact or incompletely digested protein molecule from the intestinal tract is regarded as the mechanism underlying food allergies. While practically any protein food customarily eaten by man may be responsible for the development of allergic sensitivity, meat appears to be one of the most infrequent offenders.

In a survey in a small community in Virginia, Vaughan* found that a large percentage of the population was afflicted with sensitivity to certain foods. Only a notably small number, however, mentioned meat as the possible allergen.

In the planning of the non-allergenic

diet, therefore, meat may play a significant role. Meat is a rich source of protein, and is available in such wide variety that some form of meat—beef, veal, lamb, pork, and meat products such as liver, sweetbreads, kidney, etc.—may be safely included in the dietary. This is particularly important since the patient showing allergic reaction to beef may not be sensitive to lamb or the other meats, and vice versa. Since other common protein foods such as eggs, milk, and cereals are the most frequent offenders, it may at times be necessary to make meat almost the only source of required protein.

*Vaughan, W. P.: *The Practice of Allergy*, p. 63, C. V. Mosby & Co., St. Louis, 1939.

The Seal of Acceptance denotes that the statements made in this advertisement are acceptable to the Council on Foods and Nutrition of the American Medical Association.

Lesson *in a* Lunchbox

WHY is it that ever since America was plunged into war people have been eating more bread?

Why is it that "standard equipment" in the lunchboxes of America's hardest workers is *bread*—bread in thick slices, bread in half loaves, bread in sandwiches, or just plain with cheese, meat, perhaps milk or tomatoes?

The answer is in the unquestioned fact that bread is *one of our best energy-foods*. Its high content of carbohydrates makes it a basic element in the diet of people who lead hard-working, active lives.

Today all of us are more active as a result of the war. If we are not actually working at harder jobs in factories, we are doing unaccustomed things that put extra drain on our energy. The businessman on air-raid warden patrol and the woman spending afternoons sewing for the Red Cross both expend more energy than they used to.

So there's this simple lesson in America's war-factory lunchboxes: *A more active America can well add more bread to its diet.*

Bread is inviting, tempting to the palate, servable in almost countless ways. Especially valuable is the new enriched white bread. While retaining all the preferred flavor, texture and color of white bread, it supplies extra Vitamin B₁, niacin and iron as recommended by the Food and Nutrition Board of the National Research Council.

A man, stepping from moderately active to active occupation, can very well add two slices per meal to his bread consumption—as well as increasing the meat, potatoes and fats he eats.

Good nutrition fits the diet to the individual *and the occupation*. With all of us becoming more active, new diets are called for.

Base them on bread—for taste appeal, variety, convenience and especially the high food-energy value of this basic food.

MOST GOOD BREAD IS MADE WITH FLEISCHMANN'S YEAST
The yeast used by most of the commercial bakers of the country is Fleischmann's. Many bakers enrich white bread by using Fleischmann's Enriched Hi-B₁ Yeast, thereby insuring an even distribution into every slice of valuable quantities of natural Vitamin B₁, niacin and iron.

Bread *is basic*

THE NEW APPROACH TO ADJUSTMENTS IN

Smoking Hygiene

● The new opportunity for patients' cooperation

● The value of keeping special case histories

THE relationship of nicotine intake to certain sub-clinical symptoms is of interest to the physician.

Time was when clinical observation in such cases was difficult. Patients were reluctant to fall in with limitations on smoking.

Now your recommendation of slow-burning Camels* is a simple step towards securing this cooperation. Millions have found an added "pleasure factor" in Camels' special mildness and unusually fine taste.

In anticipation of more accurate data when adjusting smoking hygiene, we suggest that you keep a separate file of these case histories. This may lead to interesting conclusions. ★

Copper-Iron

Compounds Needed
in the Battle of
Production

Women war workers — more susceptible to Nutritional Anemia than the men they replace—create serious industrial problem

With more and more women going into war work in factories or in the auxiliary services, nutritional and secondary anemias must be considered as obstacles to our ultimate Victory.

These ailments will cause lowered production, fatigue, mistakes, substandard work, spoilage, malingering and absenteeism.

We must not have a "slow down" when a "speed up" in war effort is imperative!

Iron Plus Copper Excels Iron Alone

Surest, quickest way to increase and maintain high hemoglobin levels, to keep women fit for the extra, unusual wartime duties is to use Foundation-licensed Copper-Iron Com-

pounds. Results are faster, hemoglobin levels are higher, recovery periods are greatly shortened when copper is provided to release and catalyze the iron for hemoglobin regeneration.

Clinical tests have repeatedly shown the superiority of Copper-Iron Compounds over iron alone.

Two Foundation Booklets contain evidence upon which preference for Copper-Iron Compounds can be soundly based. *Send for them now.*

This Seal, or the imprinted Foundation name, is assurance that licensed Copper-Iron products so identified are approved upon periodic tests.

ALL KELLOGG CEREALS ARE THE KIND RECOMMENDED BY UNCLE SAM

Hitch your good nutrition
program to the stars of the
American breakfast table

● Be glad that Kellogg Cereals appear so frequently on the tables of so many of the people you are trying to aid in your work for better nutrition. That's one eating habit you won't have to change! For every Kellogg Cereal is made of whole grain, or is restored to whole

grain levels of vitamin B₁ (Thiamin), Niacin, and Iron. This means that all Kellogg Cereals meet the recommendations of the U.S. Official Nutrition Food Rules.

If you want to accomplish your good nutrition program swiftly, why not hitch it to the Kellogg stars?

QUESTION: *I have noticed that green, leafy, and yellow vegetables are listed as excellent sources of vitamin A. Is this true of canned vegetables or only of fresh, raw products?*

ANSWER: The vitamin A activities of these vegetables, or for that matter foods in general, are not adversely affected by canning (1). The heat treatments employed in blanching and "cooking" of canned vegetables destroy the enzymes in these vegetables; and the permanently sealed can protects the food from the air during storage and distribution. Hence, frequent consumption of green, leafy, or yellow vegetables, either fresh or canned, may be relied upon to supply important amounts of vitamin A (2).

DIPHTHERIA TOXOID ALUM PRECIPITATED— WHOOPING COUGH VACCINE COMBINED SQUIBB

DIPHTHERIA and whooping cough are considered two of the most serious infectious diseases of early childhood.

Specific preparations for their prevention are available either as individual products or in combination. The combination product was used by the Newark City Health Department in the immunization of 840 children. Two injections of 1 cc. each given with an interval of one to two months afforded a high degree of protection against diphtheria and apparent protection against whooping cough. At present it is recommended that 3 or 4 injections of 1 cc. each be given at monthly intervals.

Diphtheria Toxoid Alum Precipitated-Whooping Cough Vaccine Combined Squibb is supplied in 8-cc. vials, each 1 cc. containing a full immunizing dose of diphtheria toxoid alum

precipitated and 10,000 million *Bacillus* (*Haemophilus*) *pertussis*.

ALSO AVAILABLE

Whooping Cough Vaccine Squibb—Contains 10,000 million killed *Bacillus* (*Haemophilus*) *pertussis* per 1 cc. Prepared in exact accordance with the method of Kendrick and Eldering. Supplied in 8-cc. and 24-cc. vials. Double strength vaccine (20,000 million killed *Bacillus* [*Haemophilus*] *pertussis* per 1 cc.) in 5- and 20-cc. vials, is also available.

Antipertussis Serum (Rabbit) Squibb—A highly concentrated, antiserum, for passive immunization of persons who have been exposed to whooping cough, especially children under 3 years of age. It may also be used in treatment and to modify the course of the disease. Supplied in vials containing 1 prophylactic dose, 15,000 (mouse-protective) units. For prophylaxis the dose is 1 vial and for therapy at least 2 vials.

To you who are taking an active part in promoting the national nutrition program...

THIS SHIELD REPRESENTS AN
IMPORTANT CONSIDERATION

All Kellogg Cereals
meet the requirements
of the U.S. Official
Nutrition Food Rules

★ Cereals . . . the right kind of cereals . . . have an important place in America's wartime nutrition program, according to the Nutrition Division, Office of Defense Health and Welfare Services.

The type of cereals specified by the Official Nutrition Food Rules are those which are *whole grain* products, or which have been restored to original *whole grain nutritive values*.

Every cereal in the famous Kellogg Line meets one of these two requirements . . . is made from *whole grain*, or is restored to *whole grain values in thiamin, niacin and iron*.

This fact should be of special significance to you. Kellogg's Cereals have long been the country's most popular favorites. They are already a breakfast *habit* with millions of American families . . . a habit that *need not be changed* for full co-operation with the nutrition program.

Moreover, Kellogg's Cereals also encourage greater consumption of milk and fruit; help save sugar, because they are pre-sweetened; help save time and fuel, because they require no cooking.

Adaptation of Public Health Programs to Defense Needs*

JOSEPH W. MOUNTIN, M.D., F.A.P.H.A.

Assistant Surgeon General, Division of States Relations, U. S. Public Health Service, Washington, D. C.

ONE of the outstanding problems facing us in the present emergency is the evaluation of tasks in the order of their importance to national defense and security.

Like many other groups, persons engaged in public health work wish to identify their normal activities with the defense effort. On all sides one hears rather dubious clichés to the effect that the prosecution of total warfare involves total defense. It is pointed out that the health level of the nation as a whole must be raised, that the educational status of the country must be improved, that the morale of the entire population must be placed upon a firmer basis. Everything we undertake—or would like to undertake—has, it seems, a direct and important bearing on defense—whether the measure be designed to increase the vitamin content of food products, to insure the birth of healthy infants, or to lengthen the span of life.

Fundamentally, of course, this concept of total defense is sound. Nevertheless, there is danger that it may result in a dispersion of effort which is ill suited to the requirements of the moment. If the nation were embarking upon a thirty year war, and could pursue it leisurely, emphasis on a comprehensive and long-range program would certainly be justified. Today, however, war is neither planned nor fought according to the protracted methods of the past. If effort is distributed over too many diversified activities, or if plans are made primarily with an eye to the distant future, the blitzkrieg is likely to overcome our country before we are well into the planning stage.

With so much to be done, so little time in which to do it, and such limited facilities for doing it, this is an occasion when things of immediate importance must come first. Health officers and others in the field upon whom the administrative responsibility falls will have to concentrate on those activities which are most important and most urgent. Stated in the simplest terms, this means

* Read before the Health Officers Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 16, 1941.

that they must give first thought to safeguarding the health of our soldiers, sailors, and workers in defense industries—those who are being trained to do the shooting and those who are providing the guns and materials with which to shoot.

The Army and Navy have their own medical and sanitary corps. Within the limits of their authority, these organizations are doing fine work in protecting the health of soldiers and sailors, but their efforts cannot be successful unless they have the full coöperation of civilian health agencies. The health and well-being of the men in the barracks depend to a great extent on conditions outside of the cantonments, conditions over which Army and Navy medical and sanitary officers have no control. Men in training spend considerable time "off post." While on maneuvers or leave of absence they travel long distances. Basic insanitary conditions or laxity regarding matters of social protection in communities frequented by military personnel may result in individual ill health or the introduction of disease into a military establishment. Even more especially, civilian health authorities have a direct responsibility for the health of the greatly increased force of industrial workers now engaged in producing essential goods. If the Army and Navy are to be supplied with the materials they need, not only must defense workers be kept on the job but also they must be kept there at a maximum level of health and efficiency.

Now, what are the chief problems encountered in adapting the health services of the country to defense needs? As far as communicable diseases are concerned, the only ones which have given any real trouble to date are the venereal infections. The coming winter, however, may provide a test of whether or not we will continue to be so fortunate in this respect. Last winter

conditions were rather favorable. Relatively few soldiers had actually arrived in the camps, and many of them were partially seasoned troops. True, large numbers of construction workers were employed in defense areas, but they were more or less inured to hard work and exposure. This winter the camps will be filled to capacity. Many of the men will be new recruits who have not developed immunity to various infections which they may encounter in their new locations. It will therefore be necessary for both civilian and military health authorities to be on the alert for every sign of communicable disease.

Except for the venereal diseases, which I shall mention again later on, the greatest tasks encountered so far have been those dealing with elementary sanitation—the provision of fundamental sanitary services such as safeguarding water and food supplies, removing garbage, and disposing of sewage. Only those who have seen the insanitary conditions of boom towns are able to appreciate problems now confronting health authorities in many localities. Almost overnight, communities have sprung up in which no facilities for sanitation have yet been provided. In other places, the sudden increase in population has rendered existing facilities altogether inadequate. To indicate the magnitude of this problem, I may cite summary findings of the reconnaissance surveys undertaken by the U. S. Public Health Service. In 184 major defense areas surveyed, it was estimated that more than 105 million dollars would be needed to provide essential water, sewerage, and garbage disposal facilities for the contained communities. This is only a portion of total needs, since many secondary defense areas are not included in the estimate. Furthermore, other major areas are yet to be established for which no prediction of sanitation requirements can be made.

In many instances it is utterly impossible for the communities in question to provide the facilities through their own resources. Take the example of a small southern town adjacent to a newly constructed military camp with a strength of about 14,000 men. Before the camp was built the town's population was 625; today it is over 5,000. Whereas there were formerly two restaurants which did little business, ten are now operating to capacity, to say nothing of about forty "juke joints" where drinks and light lunches are served. The town had no local health organization whatever. There was no sewerage system. Public toilet facilities were limited to two single toilets in the basement of the courthouse, and these were restricted to use by white persons. Several artesian wells provided drinking water, but because of a marked sulfurous taste the townspeople preferred the water from a shallow well in the courthouse square, which was found to be heavily contaminated from a nearby cesspool. The artesian wells flowed continuously from unfauceted pipes and drained into the surrounding lowland where malaria-bearing mosquitoes bred in profusion.

To meet the critical situation in which this town suddenly found itself, at least \$80,000 was needed for a sewerage system, \$25,000 for water supply and distribution, \$20,000 for a health center, and about \$15,000 a year for the maintenance of a local health department—a total of \$140,000. But the aggregate income from taxes during 1939 was only \$720! The income during 1940 was said to be more—about \$1,200. Nobody was quite certain of the amount because there had not been enough money to hire an auditor.

Nevertheless, prompt action was imperative. With the emergency health and sanitation funds provided by Congress, the Public Health Service made available through the state health de-

partment a commissioned medical officer to organize an emergency local health department. Assisting him were an engineer, a nurse, and a clerical worker provided by the state and county. They are still there, working under the direction of the state health department. All four of them and their equipment are crowded into the eight by twelve foot jury room, a small section of which has been curtained off for clinical purposes. When a jury convenes, the health department simply moves out. By scheduling field work on these occasions, this resourceful health officer makes a partial adjustment to a rather unsatisfactory office arrangement.

In the short time of its operation this rudimentary health unit has done remarkable work. With the aid of county funds and WPA labor, a modern comfort station has been erected in the center of town. Malaria control measures have been instituted and supervised. Dairy and restaurant inspection has been rigidly maintained, and today elementary sanitation is provided even in the "juke joints." The town officials were induced to apply a sledge hammer to the housing of the contaminated courthouse well, and to seal the well with concrete. A venereal disease clinic has been established, and close coöperation is maintained between military and civil authorities in prostitution repression, case reporting, and contact tracing. These activities represent only a beginning. With proposed improvements such as an adequate water supply, a sewerage system, and a health center—now possible through funds provided by the Community Facilities Act recently passed by the Congress—this town will be assured fundamental measures for protection of health.

Problems similar to those encountered in this small southern community exist in many other defense areas throughout the country, and are being met in a similar way. While the initial capital

grants for the additional facilities and services will have to be provided in most instances by the federal government, many of the communities which will benefit by defense activities should eventually be able to assume a major share of the financial burden. The increase in population, business, and property values will provide a basis for tax income which can be utilized to pay for and operate the improvements.

But there are several obstacles beside lack of funds. The health organization of this country is complex, uneven, and diversified. Administrative jurisdictions overlap and sometimes conflict. In many localities health laws and ordinances are lacking; in others they are inadequate. In some places enforcement of existing laws is not seriously attempted. Many defense establishments are of necessity situated in rural or semi-rural areas where zoning regulations to determine the uses of property have not even been thought of. In such areas a person is at liberty to set up almost any kind of establishment he wishes, wherever he wishes, and operate it as he pleases. As a result, the usual practice of health authorities is to wait until an intolerable situation has developed and then hail the operator into court for maintaining a nuisance. Many situations of this type can be prevented if health officers will exercise foresight and see that needed restrictions are enacted and put into effect. Where proper health regulations are nonexistent or where they are not enforced, correction can often be achieved by having the military authorities declare the offending establishments "out of bounds." This has had a prompt and salutary effect in most instances, but it is a "last resort" measure and is equivalent to an admission that civil government has failed. Another stumbling block, legal in character, arises from low debt ceilings and lack of authority to issue bonds for public improvements, especially

bonds to be retired by income from use of the proposed utilities. Further difficulties result from the absence of legislation which would enable public bodies to operate facilities even though they may be constructed as outright grants. There are, for example, areas in which no public agency has authority to construct or operate a hospital. In some states, cities and counties cannot maintain a hospital jointly. An aggregation of dwellings gives rise to need for sanitary facilities, but unless this population group forms a body politic, it is not in a position to construct or operate such facilities. State and local health departments should have been aware of these legal deficiencies, but apparently they were not; they even neglected to act after being warned by federal agencies, and when the emergency arrived, many were wholly unprepared.

The greatest problem of all, however, is the shortage of properly qualified and trained personnel. If all other difficulties could be resolved at once through the acquisition of facilities and organizational framework necessary for the task—health agencies would still lack trained man power. One need not have the gift of prophecy to foretell that the personnel problem of health departments will become more acute as the defense effort of the nation is increased.

Since 1936 an extensive program of postgraduate training for public health personnel has been carried on with funds made available to the states by the Federal Social Security Act and the Venereal Disease Control Act. In these five years both the quantity and quality of professional health personnel have increased very markedly. Nevertheless, the supply is still inadequate. Last April, with emergency funds voted by Congress, the Public Health Service began to recruit and prepare public health workers for special defense activities. After a short period of orientation in which the re-

sources of the National Institute of Health are used, these workers—physicians, engineers, nurses, and laboratory personnel—are assigned by the Service to communities where they are most urgently needed. They are paid with federal funds, but are responsible directly to the state or local health departments to which they are assigned. In so far as possible an effort has been made to enlist persons who are not already employed by state or local health agencies, but sometimes it becomes necessary to depart from this practice because federal civil service regulations require that persons be accepted from established registers. Our aim has been to provide highly mobile units which can be utilized to speed the defense program in critical locations. To date, 426 professional workers, including 98 members of the regular and reserve corps of the Public Health Service, have been detailed to general health and sanitation work, industrial hygiene, and venereal disease control activities. Comprising the total are 94 medical officers, 171 engineers, 112 nurses, and 49 laboratorians and specialists. To these will be added others. As soon as one group of recruits has completed the orientation course, another group is ready for induction. This process will be continued until the more pressing needs have been satisfied.

Of course, this emergency orientation program of the Public Health Service hardly does more than scratch the surface of the total personnel problem. It is hoped, however, that existing methods may be incorporated into a more comprehensive system that will meet health demands not only within special defense areas but also throughout the nation.

In the main, essential health services for the general civil population throughout this country will have to be provided by the states and communities themselves. State training programs must be continued, but this alone will not be

enough. There are two other ways in which the disparity between personnel needed and available can be at least partially resolved. First, health departments must enlarge the scope of their training activities. Second, when necessary they must dilute their staffs with personnel whose qualifications and training are of a somewhat lower grade than would be acceptable under normal circumstances. It is not meant that persons who are wholly untrained should be employed, but rather that some partially trained workers will have to be utilized for the duration of the emergency. It may be necessary to apply similar dilution throughout the entire organizational structure of our health units. This statement does not imply that merit systems of personnel administration should be disregarded. It is possible to adapt merit systems to current needs by setting up interim classifications in which persons with lesser qualifications may be hired on a temporary basis to meet urgent needs. Thus, if three engineers are needed in a community where only one is available who meets the qualifications for the title "sanitary engineer," a lower classification such as "acting sanitary engineer" or "sanitary engineering aid" might be set up to permit temporary employment of the other two.

Consideration must also be given to enlargement of function. Health departments have traditionally regarded themselves as educational and law-enforcement agencies. They have been content to find out what ought to be done and to tell others how to do it. Operation of facilities has been shunned even when the facilities bore a direct relationship to the health of the community. This attitude is not suited to the present emergency. If some essential tasks are to be accomplished at all, health departments will have to break a few precedents and do them—with their own personnel. They may be re-

quired to operate new water and sewerage plants as well as hospitals and clinics. They may also find it necessary to assign engineers and others from their staffs to operate facilities from which regular personnel are called for military duty.

An old problem which has placed a tremendous burden upon health departments is control of the venereal diseases. This has always been a source of trouble during periods of military mobilization, and the present is no exception. Since the last war, our resources for combating these diseases have been materially increased by the development of new therapeutic methods, but improved therapy is not the complete answer; it must be accompanied by vigorous repression of prostitution and effective contact tracing. Furthermore, repression and contact tracing on a local basis are not sufficient. Prostitutes who are compelled to leave one town or county quickly invade the neighboring ones. Even state-wide action is not enough by itself. Present-day transportation facilities which enable both prostitutes and their patrons to move readily from place to place add greatly to the difficulties of contact tracing. Health units today should be staffed and equipped so that they can coöperate in venereal disease control work with military and civil health authorities not only in nearby jurisdictions but also in distant places. Again this requires additional personnel. So does coöperation with welfare authorities, which is essential if the itinerant and local girls who engage in casual prostitution are to be reclaimed before they become confirmed in the profession. The chances for rehabilitation of these girls would be greatly increased by the provision of suitable places of detention where they could be treated and given training for useful pursuits. Penal institutions not only are inadequate but are altogether unsuited to this purpose. Here, too, it is hoped that by means of

funds made available through the Community Facilities Act some such accommodations can be provided, preferably in conjunction with appropriate state institutions.

The defense program has also made it necessary to give increased attention to industrial hygiene. The effective use of modern machines calls for efficient workmen. It is estimated that even in normal times the nation loses about 350,000,000 man-days a year through all types of industrial disability. A substantial proportion of this disability is caused by circumstances arising out of the nature of the job or the conditions of the working environment. Acceleration of production for defense has intensified existing industrial hazards and created some new ones. The fatigue factor which is responsible for so many costly accidents has assumed greater importance than ever before. Sanitary, safety, and medical care facilities have had to be provided in hundreds of new and expanded defense establishments. It has been necessary to investigate the potential hazards involved in the use of new materials and processes, and to develop safeguards when needed.

A special effort has been made to establish and strengthen industrial hygiene divisions in state and local health departments. Included among the emergency health and sanitation personnel previously enumerated are 26 trained persons loaned by the Public Health Service to aid these divisions in their work. Also mobile units of specially qualified physicians, engineers, and chemists have been provided to conduct surveys and make recommendations in places where states did not have the necessary resources. The Public Health Service has also surveyed arsenals and other industrial establishments operated by the War Department and is now conducting investigations in government-owned but privately-operated defense plants.

Another important task with vital bearing on our national security is physical rehabilitation of young people throughout the country—the group on whom the nation must rely for both its military and industrial man power. Some health authorities frequently extol the United States as the healthiest nation in the world. If anyone is impressed by complacent generalities of this sort, the figures showing the rejections for selective service ought to disabuse him. We may be a healthy nation in respect to communicable disease rates, but according to any absolute physical standard there is certainly no reason to be proud. Since the draft examination data were made public, there has been considerable discussion of rehabilitation, but little has actually been accomplished. These findings represent a general problem which public health authorities must face, but so far as I am aware no comprehensive state program has even reached the planning stage.

Let me add here that at the outset of the national emergency, the Public Health Service assigned one of its medical officers to the headquarters of each Army corps. This assignment has greatly facilitated operations of the health aspects of the entire defense program. Furthermore, it has served to bring the military authorities, particularly the medical corps, into close touch with state and local health workers and thus has given a measurable impetus to public health activities in general. Appropriate credit is due the state health authorities and the local communities for their efforts to cope with the emergency. This effort is expressed by the diversion of approximately \$1,689,000 federal and state grant-in-aid funds to defense areas and by the appropriation of \$639,000 of new money by the localities concerned. This, of course, does not take into account budgets for the support of preëxisting health organizations.

CONCLUSION

In conclusion, it should be said that as the national emergency grows more acute we of the public health organization may not be able to do everything that is considered desirable for all groups of the population. In some instances customary activities will have to be curtailed in order to devote time and effort to immediate defense tasks. It may be necessary to go farther than this; health departments may have to share their personnel with other agencies even more generously than they have to date. If health officers whose departments are already under-staffed feel that this is asking too much, I would ask them to consider the predicament of an Army post surgeon to whom I spoke several months ago. In the area around his camp, all the chaos associated with construction prevailed. An epidemic of influenza was threatening, and some 20,000 fresh troops were scheduled to arrive. Yet there was not a single physician, engineer, or nurse with public health training under the command of this medical officer. As a matter of fact, all there was in the way of public health organization was a single veterinarian who in civil life specialized in the care of pet animals. The post surgeon was not very happy about the prospect. This, of course, represents an extreme situation during the early organization of the defense program. Needs, less dramatic but perhaps equally important, exist today, and they are certain to increase in number as the emergency requirements increase. When demands for trained personnel arise in the military establishments, they must be filled at once, even though doing so means taking people away from other jobs. As a group, we must be prepared to abide by certain priorities in health work just as we do in regard to iron, steel, rubber, and other vital defense needs.

Eventually our efforts, if properly

directed in this emergency, will redound to our permanent benefit as well as to that of the nation.

When the crisis is over, some of the additional facilities established for the emergency will probably be dismantled, but many of them will remain in use. The tradition of essential service will endure under all circumstances. As a

result, the health organization of the country as a whole will be on a higher level than it was before. We will then be in a better position to develop some of those optional services having to do with improving the health status of the general population. Until then, first things will have to be placed first on the agenda.

WANTED: The following issues of the *American Journal of Public Health*—April, 1911; February, 1937; January, 1938; February, 1939; July, 1941; and August, 1941. The American Public Health Association will be glad to pay postage for the *Journals*.

Mobilization of Industrial Hygiene for National Defense*

W. J. McCONNELL, M.D., F.A.P.H.A.

Metropolitan Life Insurance Company, New York, N. Y.

SCARCELY more than a quarter of a century has passed since industrial hygiene has attained recognition in America as a special field of endeavor for maintaining and promoting the health of industrial workers. Prior to this period, emphasis was placed on the surgical treatment of injuries and the alleviation of illness rather than on preventive measures. Frequently the emergency care of injuries was the only motive for providing medical services.

Many factors have contributed to our present broader concept of medicine's serviceableness to industry. Not least among these were the courageous efforts on the part of a small group of men with a keen sense of responsibility to their fellow men who, despite little general interest on the part of professional groups in the subject, banded themselves together through the Industrial Hygiene Section of the American Public Health Association, the American Association of Industrial Physicians and Surgeons, and other organizations for the purpose of fostering the study and discussion of the problems peculiar to the field of industrial hygiene.

By an Act of Congress passed in 1912, the U. S. Public Health Service was authorized to "extend its research functions to the study and investigation

of all diseases of mankind and conditions influencing the propagation and spread thereof." As a result of the passage of this Act, the Service established in the Marine Hospital at Pittsburgh, Pa., during the year 1914, the Office of Field Investigations into Occupational Diseases. The name was changed in the following year to the Office of Field Investigations in Industrial Sanitation and the office was transferred to Washington in 1918. The creation of this office in the U. S. Public Health Service marked an important forward step in the advancement of industrial hygiene. The improvement of industrial health became in this way a national concern.

During the year 1914 the Industrial Hygiene Section, the fifth of the present ten sections of the American Public Health Association, was organized. The Conference Board of Physicians in Industry also was established in 1914. This Board acted in an advisory capacity to the National Industrial Conference Board. The following year saw the organization of the American Association of Industrial Physicians and Surgeons. In 1920 the American Medical Association recognized the existence of this special field by merging industrial medicine with preventive medicine and public health in the Scientific Assembly. It was not until 1937, however, that the governing bodies of the American Medical Associa-

* Chairman's Address delivered before the Industrial Hygiene Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

tion organized the Council on Industrial Health as a standing committee of the Board of Trustees. Since its organization the Council has made important contributions to industrial health. It has been active in stimulating the formation of committees on industrial hygiene in state and county medical organizations, and has established working relations with all agencies interested in industrial health.

During the 1st World War impetus was given to industrial hygiene through national agencies. The creation by act of Congress in 1916 of the Council of National Defense, which provided for the appointment by the President of an advisory commission, resulted in the formation of a number of committees and subcommittees not unlike those of today. One of these subcommittees, known as the National Committee on Welfare Work, issued a series of reports aimed at aiding employers in the vital industries to maintain and conserve the health and efficiency of their workers through improved working and living conditions and improved training methods. During this period personnel of the U. S. Public Health Service was detailed to the Working Conditions Service of the Department of Labor and functioned under the name of the Office of Industrial Hygiene and Medicine. The personnel of this office supervised the sanitation and medical service in as many of the industrial establishments owned or operated by the federal government as was possible with the limited personnel assigned to carry out these functions. This cooperative work with the Department of Labor was discontinued in 1919 because of lack of funds, and the organization reverted to the U. S. Public Health Service. The name was again changed to the Office of Industrial Hygiene and Sanitation, which is now the Division of Industrial Hygiene and Sanitation, located at Bethesda, Md. The excellent record in scientific

investigations in a number of occupations and dangerous processes made by the Public Health Service through this division is well known.

Other federal agencies, particularly the U. S. Bureau of Mines and the U. S. Department of Labor, have been active in this field and have conducted numerous investigations and laboratory research which have thrown light on some of the pressing problems affecting the health of workers in a variety of industries and mines.

During the intervening years many national and local associations, either wholly or partly devoted to the advancement of industrial hygiene, have contributed to our knowledge in this field. A few of the universities began to offer courses in subjects pertaining to industrial hygiene, and some of the insurance companies engaged personnel to assist their insured industrial organizations with a solution of their health problems. While time will not permit even a brief review of the various activities of these agencies, their contributions have been many and have served to focus attention on prevention as a cardinal principle for reducing the incidence of disability, whether through accident or disease.

The organization of industrial hygiene departments in many of the states and in some municipalities has made available to industry a valuable service which will be increasingly used as their work is demonstrated. As recent as ten years ago only a comparatively few states offered this service to industry, while today 34 states and 4 cities, aided where necessary by federal funds and by personnel from the Division of Industrial Hygiene of the National Institute of Health, have well organized departments.

These and other factors, such as the passage of state compensation acts for occupational injuries, the accident prevention movement, the acceptance on the part of enlightened management of

the principles on which health services to industry are based, and, more recently, the enactment of the occupational disease compensation laws in many states, have all contributed to the expansion of health facilities in industry and have pointed to the necessity of conducting research in fields which offer greater promise in reduction of disease and suffering.

Today industrial hygiene is recognized generally as a part of a good public health program, and may be defined as that branch of the medical, engineering, chemical, and nursing sciences which is concerned with the study of the effects of environmental conditions in industry upon the health of industrial workers from the point of view of the incidence, the causes, and the nature of the effects, and with the means of eliminating or minimizing the causes, and thus removing or modifying the effects. Industrial hygiene also is concerned with the general effects of industrial life on the incidence of all diseases, and aims at rendering the industrial worker safe, healthy, and efficient.

This brief summary of the development and scope of industrial hygiene activities is recounted for the purpose of indicating the progress of the industrial health movement and of pointing out the chief industrial hygiene resources of the country.

In the mighty defense effort in which we are now engaged, the mobilization of these resources, as well as careful planning of new activities and the training of additional personnel must be given a conspicuous place in the national defense program. The reason lies in the fact that wars which were formerly fought between armed forces on a restricted battlefield have given way to total war and total defense, where industrial capacity is more important than arms, and where adequate man power in vital industries is a major military factor. The very urgency of our de-

fense requirements has emphasized the need for a well planned program of industrial hygiene for the protection and conservation of health among defense workers.

The importance attached to an effective health maintenance program was stressed by Dr. Daniel L. Lynch in his presidential address before the Association of Industrial Physicians and Surgeons last May when he said:

The industrial workers' physical fitness, their freedom from preventable disease and injury, their morale or mental stamina, their ability to achieve for national defense, will determine almost entirely the effectiveness of all other efforts. Desirable in the easy days of peace when no cloud of war blackened the horizon, it is imperative now that the workers in industry, especially, "must be physically tough, mentally sound, morally strong." If they are not, we can leave our planes unbuilt, our battleships in blueprint. We shall not need them.

It remains to be seen how well those responsible for planning and directing an industrial health program have met this challenge, and similarly how we in the industrial hygiene field have responded to the call for service with all the increased opportunities and responsibilities that are ours.

The mobilization of the medical and health resources of the nation and the responsibility for coordinating all health and medical programs affecting the national defense found expression first through the creation on September 19, 1940, of a Health and Medical Committee by the reestablished Council of National Defense. Later, the Council, by Executive order of the President, transferred the Health and Medical Committee to the Federal Security Agency for the purpose of advising and assisting the Administrator in carrying out his duties as Coordinator of Health, Medical, Welfare, and Related Activities.

One of the first acts of the Health and Medical Committee was the appointment of six subcommittees, each

representing broad segments of medical interests. Of particular interest to this group is the Subcommittee on Industrial Health and Medicine under the able chairmanship of Dr. C. D. Selby. This subcommittee is charged with the duty of making specific recommendations pertaining to activities in this particular field to the Health and Medical Committee.

The Subcommittee on Industrial Health and Medicine has been transferred within the past month to the Office of Health Defense and Welfare Services in the Office for Emergency Management, under the directorship of Paul V. McNutt, following the creation of this new organization on September 3, 1941, by President Roosevelt. The members of this subcommittee also have been appointed as a Committee on Industrial Medicine of the Office of Scientific Research and Development of the National Research Council.

An early recommendation of the subcommittee was that the Division of Industrial Hygiene of the National Institute of Health, because of its years of research and experience in this field and its close relationship with national, state, and volunteer agencies either directly concerned or interested in the industrial health problems of national defense, assume the leadership in a program for achieving the defense objectives. Other specific recommendations made by the subcommittee called for an expansion in personnel facilities and funds of state bureaus of industrial hygiene and the Division of Industrial Hygiene of the National Institute of Health; the training of large numbers of personnel in industrial medicine, hygiene, and nursing; the safeguarding of the health of workers employed in the industrial organizations of the War and Navy Departments; and further researches into new industrial processes which might be injurious to the health of exposed workers.

These recommendations were approved and at the present time are being carried out. In order to facilitate the work, Surgeon General Parran has created a new section in the Division of Industrial Hygiene of the National Institute of Health, with Sanitary Engineer J. J. Bloomfield in charge. This section is concerned with all national defense activities and states' relations in industrial hygiene.

The activities of this section as well as those of the section on industrial hygiene research, in charge of Dr. Paul A. Neal, are being carried out under the general direction of Medical Director J. G. Townsend, Chief of the Division of Industrial Hygiene.

The work of the division has been supplemented with fifteen teams or units, each unit consisting of a specially trained physician, an engineer, and a chemist, with additional personnel as required, serving as mobile field units available to go anywhere in the country to survey health hazards in war industries and to provide consultation service, in coöperation with the state and local health departments, to any defense industry requiring such assistance.

The accomplishments already attained by the Division of Industrial Hygiene of the National Institute of Health in the field of industrial hygiene and in the toxicological research on defense materials, and by studies on the effects of physical and other environmental factors, particularly those of an emergency nature, as well as the many accomplishments of state industrial hygiene units which are all engaged in furnishing services to defense industries, have been described on several occasions elsewhere and need not be enumerated here.

Coöperative programs with other divisions of the Public Health Service and with various other governmental bureaus, as well as with independent agencies, will bring to the industrial

worker the benefits of all the adult health services.

The American Standards Association, through its Sectional Committee on Allowable Concentrations of Toxic Dusts and Gases, is coöperating with the Division of Industrial Hygiene of the National Institute of Health in the preparation of technical standards for the prevention of industrial diseases. Codes have already been adopted and printed for benzol, hydrogen sulfide, carbon disulfide, and carbon monoxide. Work is actively under way on codes for many additional substances that are dangerous to health. The association also is engaged in the preparation of a wide variety of standards for use in the national defense program. The Standards Council has devised a method for quick action in developing emergency standards for defense purposes which will make it possible to turn out standards needed to speed along defense production as rapidly as is consistent with a good technical job.

The American Medical Association, through its Committee on Medical Preparedness, appointed in June, 1940, has made available every facility that the association can offer for the health and safety of the American people. A most important activity undertaken by the committee consisted of assembling a complete roster of the medical personnel of the United States and its possessions for the purpose of determining the number of physicians available for service in various capacities. To every physician who indicated active participation in industrial medical work, the committee sent an additional inquiry designed to acquaint the committee with the special qualifications which individual physicians possess and also certain details about industrial medical facilities which they command. It is of interest to note that this is the first time in the history of our country that an effort has been made to obtain this

exceptionally useful information. In addition to the services conducted by the Association's committee on Medical Preparedness, the Council on Industrial Health of the Association has been active in carrying out its program of industrial health and is making a real contribution in this field. A joint committee of the Council on Industrial Health and the Subcommittee on Industrial Health and Medicine was formed last January to make recommendations to the Health and Medical Committee of the Federal Security Agency covering industrial hygiene needs of national defense.

The National Research Council, which was established in 1916 as the operating agency of the National Academy of Sciences, and was perpetuated at the end of the war in 1918 through an Executive order issued by President Wilson, is an important quasi governmental organization now permanently established to give advice to the government "on any subject of science or art."

The Council through its Division of Medical Sciences established during the summer of 1940 a number of advisory committees covering the fields of medicine, surgery, and information, as well as a number of technical subcommittees. The work of a number of these committees has a direct bearing on industrial medicine—the research project on the prevention of wound infection and the treatment of burns conducted by the Subcommittee on Surgical Infections; the projects dealing with all aspects of shock under investigation by the Subcommittee on Shock; the study of problems on aviation medicine conducted by the Committee on Aviation Medicine; the study of problems of neuropsychiatry to be carried on by a committee on neuropsychiatry now in the process of organization; and the investigations on fatigue, pressure studies, clothing for high and low temperatures, gas poisoning, and other subjects being conducted by appropriate committees and various

laboratories under the Subcommittee on Clinical Investigation serving as a clearing house for information are of particular interest to industrial medical groups. The appointment of the chairman of the Committee on Medical Research and Development of the National Research Council, as a member of the Health and Medical Committee has facilitated the correlation of these various committees with the general coördinating body. In a number of the projects carried on by the National Research Council, the facilities of the American Medical Association, the American College of Physicians, and of the American College of Surgeons are being used to advantage.

Of the associations representing the industrial hygiene engineering field which have been most active in the National Defense Program, the American Association of Industrial Hygienists, which meets annually with the American Association of Industrial Physicians and Surgeons, and the Industrial Hygiene Section of the American Public Health Association are representative. Many of the universities through their industrial engineering departments, and several independent agencies too numerous to comment on in the time at my disposal, are actively engaged in this field and are additional sources from which the nation can draw for assistance and

advice. Included in the list of these independent agencies are those industrial organizations which, either through their own research laboratories or their financial support of other agencies, are carrying on a variety of investigations relevant to employee health.

The Industrial Hygiene Foundation of America, formerly known as the Air Hygiene Foundation, is one of the agencies supported by industry which is directing its efforts on problems of immediate practical importance in the national emergency. This organization also is providing funds for research projects assigned to other research laboratories.

The mobilization and the establishment of effective working relationships between these many independent organizations and governmental agencies are functions of the Subcommittee on Industrial Health and Medicine. The intelligent and aggressive manner with which the Subcommittee on Industrial Health and Medicine is pursuing its program may be expected to bring full employment of our industrial hygiene resources, and it is hoped that when the threat of war has passed and peace again comes to the world the objectives reached will become an integral part of a permanent procedure which can be applied to industry generally in the years that lie ahead.

Urgent Problems in Nutrition for National Betterment*

W. H. SEBRELL, M.D., F.A.C.P., F.A.P.H.A.

*Chief, Division of Chemotherapy, National Institute of Health,
U. S. Public Health Service, Washington, D. C.*

THE problems in nutrition which are urgent today are not especially those of research in physiology and biochemistry—problems in these fields, although of the greatest fundamental importance, cannot be regarded as urgent in the face of conditions in the world today. Fortunately, we have enough information in these fields to be able to give with a fair degree of accuracy recommendations as to the daily allowances of the various dietary essentials for normal individuals. In this connection I especially want to call your attention to the recommendations recently proposed by the Committee on Food and Nutrition of the National Research Council (Table 1). These recommendations are the best obtainable today and should be used by everyone interested in calculating diets. Therefore, although there are many important problems still to be solved in determining the human requirements for various dietary essentials, we do have enough information for practical use in developing an adequate nutrition program.

There are many problems in the physiology and biochemistry of nutrition which are highly important. We need the answers to such questions

as the rôle of deficiencies in resistance to infectious disease—What is the relation between vitamins and hormones? What are the specific enzyme systems in which the various vitamins participate? What metabolites are involved? Do we know all of the vitamins? Many other similar problems of equal importance could be listed, but the problems that I regard as really urgent lie in the field of *application* of the fundamental knowledge we now possess.

Now as never before we are awakening to the fundamental importance of adequate nutrition in maintaining health. All health officials must realize that today no health program can be complete unless it includes a consideration of nutrition, and one of the most urgent problems in nutrition is how to get every health department in this country to include nutrition as an important part of its activities. A few years ago we complacently thought that there was little of the deficiency diseases in the United States because our death reports revealed few deaths from these diseases. One of our big unanswered questions today is how much deficiency disease exists in this country. We still are unable to say with certainty, because deficiency diseases usually are not reported, the death rate is very low, and the diagnosis is often uncertain.

Another of our important problems

* Read before the Food and Nutrition Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 15, 1941.

TABLE 1
RECOMMENDED DAILY ALLOWANCES FOR SPECIFIC NUTRIENTS*
Committee on Foods and Nutrition, National Research Council

	Calories	Protein grams	Calcium grams	Iron mg.	Vitamin A*** I.U.	Thiamin (B ₁) mg.**	Riboflavin mg.	Nicotinic Acid mg.	Ascorbic Acid mg.**	Vitamin D I.U.
Man (70 Kg.)										
Moderately active	3000	70	0.8	12	5000	1.8	2.7	18	75	***
Very active	4500	2.3	3.3	23
Sedentary	2500	1.5	2.2	15
Woman (56 Kg.)										
Moderately active	2500	60	0.8	12	5000	1.5	2.2	15	70	***
Very active	3000	1.8	2.7	18
Sedentary	2100	1.2	1.8	12
Pregnancy (latter half)	2500	85	1.5	15	6000	1.8	2.5	18	100	400-800
Lactation	3000	100	2.0	15	8000	2.3	3.0	23	150	400-800
Children up to 12 years:										
Under 1 year#	100/Kg.	3-4/Kg.	1.0	6	1500	0.4	0.6	4	30	400-800
1-3 years##	1200	40	1.0	7	2000	0.6	0.9	6	35	***
4-6 years	1600	50	1.0	8	2500	0.8	1.2	8	50	..
7-9 years	2000	60	1.0	10	3500	1.0	1.5	10	60	..
10-12 years	2500	70	1.0	12	4500	1.2	1.8	12	75	..
Children over 12 years:										
Girls, 13-15 years	2800	80	1.3	15	5000	1.4	2.0	14	80	***
16-20 years	2400	75	1.0	15	5000	1.2	1.8	12	80	..
Boys, 13-15 years	3200	85	1.4	15	5000	1.6	2.4	16	90	***
16-20 years	3800	100	1.4	15	6000	2.0	3.0	20	100	..

* Tentative goal toward which to aim in planning practical dietaries; can be met by a good diet of natural foods. Such a diet will also provide other minerals and vitamins, the requirements for which are less well known.

** 1 mg. thiamin equals 333 I.U.; 1 mg. ascorbic acid equals 20 I.U.

*** Requirements may be less if provided as vitamin A; greater if provided chiefly as the pro-vitamin carotene.

Needs of infants increase from month to month. The amounts given are for approximately 6-8 months. The amounts of protein and calcium needed are less if derived from breast milk.

** Allowances are based on needs for the middle year in each group, (as 2, 5, 8, etc.) and for moderate activity.

*** Vitamin D is undoubtedly necessary for older children and adults. When not available from sunshine, it should be provided probably up to the minimum amounts recommended for infants.

is how can we diagnose early deficiency disease. Although we do not know how many cases of the deficiency diseases we have, we do know from the number of cases seen by such clinicians as Wilder, Sydenstricker, Jolliffe, Spies, and others that these cases are very common. Fortunately, we have in addition the extensive dietary surveys of Stiebeling and her associates which show that a large proportion of our population, at least one-third or more, get diets which do not come up to the accepted standards of adequacy in one or more of the dietary essentials. Furthermore, as more and more clinical studies are being conducted, we are learning that deficient diets—short of producing the symptoms of a full blown deficiency disease—may be responsible for such vague symptoms as mental depression, indigestion, easy fatigue, loss of weight, retarded learning ability, and interference with vision. We need more information in order to clarify fully the importance of such symptoms. However, with the information already at hand we can no longer ignore in our health programs conditions which may be affecting such a large proportion of our population. A few years ago Surgeon General Parran said, "Food will build a new America," and food *can* build a new America if we will let it. With the development of nutritional science so rapidly unfolding year by year, we can be absolutely certain that intelligent and widespread use of that knowledge cannot fail to build a new America.

NUTRITION IN THE ARMED FORCES

In a world at war or preparing for war, the problems of greatest urgency are those affecting the armed forces, and first of all come those problems concerned with the actual feeding of the men under arms. The health officer is not directly concerned with those problems. They are recognized and are

receiving adequate consideration by the military forces themselves. I believe that our military men will be as well fed as present-day nutritional science can feed them.

The problem of next importance is that of the physical condition of prospective candidates for military service. You have, no doubt, read the distressing accounts of the large number of young men being rejected for military service. General Hershey stated at the National Nutrition Conference in May that out of a million men examined by Selective Service and about 560,000 examined by the Army, a total of 380,000 were found unfit for general military service, according to present standards. This is approximately 24 per cent. He also stated that it had been estimated that perhaps one-third of the rejections were due either directly or indirectly to nutritional deficiencies. These shocking findings are a reflection of our failure to give adequate attention to nutrition in our health programs.

The *Chicago Times* recently (August 12, 1941) published an analysis of the number of draft rejections in Chicago by wards. This analysis showed that the percentage of rejections varied from a low of 39.9 per cent in the nineteenth ward to a high of 71.1 per cent in the eleventh ward. I know that you will not be surprised when I tell you that the eleventh ward with its 71.1 per cent of rejections is considered to be one of the poorest wards in the city, while the nineteenth ward with its 39.9 per cent of rejections is a well-to-do section of the city. We must recognize that many factors have resulted in this great difference. However, when it is remembered that there is a close association between low income and deficient diets, how can there be doubt that poor nutrition played a part in producing its share of those 71.1 per cent of rejections. With such a situation existing, and there is no reason to believe that

the situation in Chicago is essentially different from that in any other large American city, the two most urgent problems are obvious. First, how many of these rejectees can we rehabilitate by proper nutrition now and what is necessary to bring this about? Second, what can we do toward preventing the development of these defects due to poor nutrition in our children?

We know now that an adequate diet is just as important in terms of human health as adequate housing, adequate sewage disposal, or adequate prevention of communicable disease. We who are in public health work are not in a position to see to it that people get or eat the right foods. We are, however, in an especially advantageous position to emphasize the value of such a program to health and to teach the great importance of these things in the maintenance of health. If we fail to do so, we will be guilty of ignoring one of the surest roads to real public health.

NUTRITION IN INDUSTRY AND AT HOME

The next most urgent problems in nutrition after those affecting the military forces are those affecting the workers in defense industries. These workers constitute our second line of defense and more is demanded of them than ever before. We know that the need for thiamin increases with increased strain and activity, and here we have thousands of workers under greater strain and activity than they have had for years, with no organized effort to improve their food supply. In addition many thousands of them have been moved from their homes into sections not prepared either to house or to feed them properly. Instead of improving their nutritive status, it undoubtedly has become worse in many instances. We find that industrial medical services have paid little or no attention to nutrition, although the time lost by workers from occupational diseases is inconse-

quential compared to the time lost from non-occupational diseases. We need to know how prevalent inadequate diets are among industrial workers, and we need to show plant managers that adequate nutrition means a more efficient, healthier, satisfied worker. Part of our industrial hygiene program, which now largely ignores nutrition, should include a study of the eating habits of the workers and recommend, where indicated, the establishment of plant dining rooms and the serving of an adequate meal at minimum cost. These constitute large problems which urgently need solving.

Finally, we come to problems of nutrition affecting the entire population. As health officials we must build for the future with a continuing program. Although military and defense problems are most urgent today, in time these men will again fit into the larger picture of our entire civil life, but now they must be sustained by a civil population of high morale and good health. The Secretary of Agriculture recently said "Food will win the war and write the peace." With these two goals ahead of us, the problems of better national nutrition become problems that we *must* solve. An understanding of this fact by farmers, government, science, and industry is, as a matter of fact, one of the first of these problems. We must realize that in the United States we are not faced with the problem of having to decide between "guns and butter." We must realize that if the United States is to bring its full weight to bear in ending the present conflict, we must supply for our country and for the other democracies both guns and butter. We must place food on a parity with guns because our food is as urgently needed by England as our planes and tanks. And when we look forward to the day when the shattered nations of Europe gather round a barren peace table, then we will see the truth

of the slogan that food will not only "win the war" but will also "write the peace."

PRODUCTION

Our great problem is to produce and to begin to produce now enough of the protective foods to meet these enormous demands. No matter how badly you need them, nothing can shorten the number of days it takes to produce a cow, a pig, or a chicken, and the time to start is now. Production is the great nutritional problem for American agriculture, and Secretary Wickard wants to make dairy products, livestock, and vegetables basic crops, as important in the nation's economy as cotton, tobacco, or wheat. He wants to build up food stocks which the rest of the world can use after the war. If we do produce these basic protective foods, there is no question but that ways and means will be found to distribute them.

DISTRIBUTION

This brings me to the biggest and toughest problem blocking the way to better national nutrition. This is the problem of distribution—of getting the food the people need to the people who need it most. This is another nutritional problem which is outside the province of the scientist and the health officer. Nevertheless, it is one which must be appreciated by anyone attempting to solve our national nutrition problems, and we must all throw our support to the agencies attempting to solve this problem. We already have the food stamp plan, the hot school lunch program, penny milk distribution, and various other channels of food distribution to those who cannot afford the foods they need. Other ways and means inevitably will be devised to distribute foods once the appetite and demand for them has been established. But regardless of these enormous economic problems which are so basic to the solution of the problem of malnutrition in

America, we must continue, each in his own field, to contribute to the solution of those phases of the problem which we are especially qualified to attack.

TEACHING WHAT TO EAT

One of the great practical problems with which you especially must be concerned is the difficulty of educating Americans to the difference between good and bad food habits. This problem has been valiantly and constantly attacked by several government agencies over a period of years. Today it is being attacked with a barrage of educational material without parallel in nutritional history, but we need your assistance also. Nutrition education should be a large and important part of every health education campaign. If your health department is not doing nutrition educational work, your health program is not complete. The problem of nutrition education is still a long way from solution. The American people still eat and cook the way they like to eat and cook, regardless of the deficiencies in their diet or the vitamins they cook away and pour down the drain. In recent years the public has obtained a large part of its nutrition education from commercial advertising, much of which has been misleading or incorrect, a condition which many health and medical men have deplored. It has become obvious since the National Nutrition Conference that the great food industries in the United States can be a powerful ally in the solution of our nutrition education problems. Up to the present, and no one can blame them, these food industries have spent millions of dollars annually to sell their products on the basis of attractiveness and taste appeal. But now, with increasing public recognition of the importance of a well balanced diet, these industries are beginning to reevaluate their products—to stress the fact that they are rich in proteins, or minerals, or vitamins, and

they are eager to have their advertising material technically correct. The question of how to coördinate and take advantage of the immense potentialities in this new attitude of the food industries is also a problem, but it is one which promises much when it is solved. The coöperation between science, government, and industry which was held up as a desirable goal at the National Nutrition Conference is daily coming closer to actuality.

One of the most valuable and successful activities has been the voluntary enrichment of white bread and flour by the baking and milling industries. This single step voluntarily taken by the bakers and millers, and publicly endorsed by the government agencies concerned, has not only made available significant quantities of thiamin, nicotinic acid, and iron in a basic and universal food item at minimum cost, but has also started a trend in food advertising and nutrition education that cannot fail to educate the American public to the values of truly "protective" foods. Furthering the distribution of enriched flour and bread in your community is not only an educational measure but also will materially help in the prevention of deficiencies in thiamin, nicotinic acid, and iron.

This problem of nutrition education then is one in which the health department should be vitally interested. I want to call your attention, however, to the necessity for coöperation in this field. There are many agencies inter-

ested in nutrition education. If your health department has neglected this field, you will probably find that other agencies have been trying to do both their job and your job too. State nutrition committees have now been organized in every state and we hope to see them become part of the state defense councils, and we hope soon to see more community nutrition committees in operation. You have a part to play in a larger program; let me urge you to contact your state nutrition committee, coöperate with your committee members, and make your program part of their plan if you have not already done so. The federal government can coördinate the program at the national level; it is up to you to bring about coördination and coöperation at the state and local levels.

In the field of public health, our duty is clear and well defined. We must accept the fact that malnutrition is one of the major causes of ill health and poor growth and development, and is one of the most important of the health officer's problems. We must realize that the problem of getting an adequate diet to the people is just as urgent a problem as keeping infection away from the people—that nutrition is truly the armour of robust health. With this conviction the public health workers in the United States can and will be where they should be—in the very forefront of the fight to vanquish malnutrition for America—which is the greatest problem of national nutrition.

Water Demands and Sewage Production in Military Cantonments

SAMUEL M. ELLSWORTH

*Lecturer in Sanitary Engineering, Harvard Graduate School of Engineering;
Consulting Engineer, Boston, Mass.*

THE design of water and sewerage works for a military cantonment, while involving the same basic engineering problems as are found in the design of municipal works, differs from the latter in the emphasis and relative importance placed upon various design features. Thus, where permanence and long life are given great weight in the design of municipal works, these factors may be of secondary importance for a military cantonment. Economic factors influence design in both cases but the emphasis is different; with a municipal works we are concerned with a business enterprise where operating costs are of primary importance, whereas with a cantonment, which may be used for only a few years, economy in construction is likely to be of greater importance than economy in operation. Moreover, reliable water consumption data to guide the engineer in the design of municipal water and sewerage works are available for most cities and towns, but such data for military cantonments are not so readily available. This paper presents a discussion of the allowances used in the design of water and sewerage facilities at Camp Edwards in

Massachusetts together with records covering the operation of these works for the past eight months.

The wholesale construction of military cantonments under the present National Defense program began a little more than a year ago. In August, 1940, it was known that Camp Edwards, formerly a National Guard training camp situated on Cape Cod in Massachusetts, was to be leased from the state as a site for a military cantonment designed to house some 30,000 troops. In anticipation of this action the Massachusetts Department of Public Health undertook certain preliminary studies looking toward the expansion of the water supply and sewerage works to meet the needs of the proposed new cantonment.

It may be of interest to compare the water consumption allowances used by the Health Department in these preliminary studies with those used later, when the design of the new works was undertaken under the direction of the Construction Division, Office of the Quartermaster General. The Health Department based its consumption allowance on that used in the design of many of the army cantonments in 1917; namely, an average consumption of 55 g.c.d. (gallons per capita daily). While it was known that some of the World War cantonments suffered occasional

* Read before the New Jersey Section of the American Water Works Association and the Engineering Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 16, 1941.

water shortages, it was felt that the replacement of horses and army mules with mechanized equipment would reduce rather than increase the water requirements. It should be said that this preliminary work by the Health Department, in which the author assisted, was undertaken with practically no knowledge of the plans and details of the proposed cantonment.

Design and construction of the new camp started a few weeks later under the Construction Division, O.Q.M.G. One of the first considerations in the design of the water supply and sewerage works was an early decision on the unit allowance for water consumption. Information on this point was sought from Washington and instructions were received to base the design of water works on an average consumption of 100 g.c.d. and a maximum domestic rate of at least twice this amount. Thus, in spite of the replacement of horses and mules with mechanized equipment, water consumption allowances had increased nearly 100 per cent over those used in 1917. No doubt a part of this increase can be attributed to the experience of World War days when camp populations increased considerably above the design figures. This, together with the fact that plumbing facilities in the new cantonments were to be more in keeping with present-day standards of living, would appear to explain the increased allowance. It will be shown from the operation records at Camp Edwards that the new consumption values adopted are not excessive.

Both the water supply works and the sewage disposal plant at Camp Edwards were designed on the basis of an average water consumption of 100 g.c.d. and a maximum consumption of twice this amount. It was not until after the design had reached its final stages, however, that standard basic data on the design of exterior utilities, in the form of a nomograph prepared by the Con-

struction Division, O.Q.M.G., became available. These standards suggested that designs be based on (a) an average water consumption of 100 g.c.d., (b) a peak water consumption for the design of pipe lines of 250 g.c.d. and (c) for the design of sewers, a peak flow of 70 g.c.d. over an 8 hour period.

For the design of sewage treatment works reference is here made to a report to the Construction Division, O.Q.M.G. submitted in December, 1940, by the engineering firms of Greeley & Hanson and Metcalf & Eddy. While this report was not available until construction of the sewage treatment works at Camp Edwards was nearing completion, the following section dealing with sewage quantities may be of interest:

The average quantity of sewage at camps and cantonments is estimated by the Construction Division to be 70 gal. per capita per 24 hours. This, in our opinion, is a reasonable quantity of sewage, perhaps high rather than low. Although most of the 70 gallons may be discharged during 16 hours, all rates are expressed on the 24 hour basis. The fact that most of the sewage flow may occur within 16 hours has been taken into consideration in the establishment of liberal detention periods based on a 24 hour average flow.

It is known that there will be sharp deviations in the rate of flow. . . . We recommend that sewage treatment projects be designed to provide for a maximum quantity of sewage, lasting for several hours of twice the average quantity, or at a rate of 140 g.c.d. Hydraulics of treatment plants and other affected parts of the design should provide maximum quantities, lasting for an hour or less, of 2.5 to 3.0 times the average, depending upon the size and arrangement of the camp and the steepness of the sewers.

The water supply at Camp Edwards is from four new 90 ft. gravel-wall wells and from some 35 small driven wells constructed in 1936 under the National Guard. The latter wells are now held in reserve for emergency use only. Four pumps drawing from the new wells have a total rated capacity of 4.9 m.g.d. However, under present conditions the pumping heads are less than were pro-

vided for in the design and these pumps are now capable of delivering water at a total rate of about 6.5 m.g.d. Storage is provided by four elevated steel tanks having a total capacity of 1.2 million gallons. The water distribution system consists of some 32 miles of cast iron mains ranging from 4" to 14" in diameter, and 15 miles of 2½" and 1½" service connections.

The sewerage system, including building connections, consists of about 40 miles of 6" to 18" sewers, all of vitrified tile except about 2 miles of cement-asbestos pipe and about ¼ mile of cast iron. Except in one pumping district, sewage flows by gravity to a 24" outfall sewer, about ½ mile in length and thence to a sewage treatment plant. All lateral sewers in regimental areas were designed to handle a maximum flow of 400 g.c.d. while main sewers on the lower part of the system were designed for a maximum flow of 300 g.c.d. The 24" outfall sewer, which was previously constructed under the National Guard, has a capacity of 230 g.c.d. when surcharged to the invert of the lowest entering sewer. These rates appear to be rather high, but they are actually lower than would have been used had certain official military advices been followed without considerable discussion. The rates are based on a population of 30,000, and in the design of both sewers and water mains a 50 per cent increase in population was always considered a possibility.

The sewage treatment plant consists of a comminutor, a grease-skimming flocculation tank, Imhoff tanks, bio-filters, and final settling tanks. The disposal of the final tank effluent is by percolation into natural deposits of sand and gravel through 12 acres of intermittent sand filters; this being the only feasible method of final disposal for this locality. The sewage treatment plant is designed for a population of 30,000, an average flow of 3.0 m.g.d. and a maximum flow of 6.0 m.g.d.

Metering equipment was provided in both the water supply and the sewage treatment works. At each of the four new wells there are an orifice meter and an integrating flow recorder. Recording altitude gauges are provided near the elevated storage tanks which give a continuous record of the volume of water in storage. At the sewage treatment works there is a control section meter, similar to a Parshall flume, to measure and record sewage flows.

So few reliable data were available for the design of water and sewer lines serving unit regimental areas that recommendations were made for the installation of meters on the water lines in one or two such areas. At relatively small cost meter records would have given valuable information regarding peak rates of water consumption in small, thickly populated areas which would have been useful in laying out future cantonments. Unfortunately, official approval for the installation of

these meters was not given and thus far none have been installed.

Water consumption records for the camp as a whole have been available since January, 1941. The daily consumption from January through August is shown in Figure 1, together with the camp population, and the estimated per capita consumption. It is seen from this chart that during the early months, when the number of troops was under 15,000, the average consumption varied from 110 to 120 g.c.d. This rate gradually diminished as the camp population increased, with a minimum consumption of 80 g.c.d. being reached during one week in April when the camp population had risen to 26,000. Later, during June, July, and the first weeks of August, when the camp population varied between 27,000 and 28,000 the consumption increased to about 95 g.c.d., based on weekly consumption records, including Saturdays and Sundays but excluding holidays. During the third week in August there was a marked drop in the camp population and water consumption, as a result of extended maneuvers of the 26th Division at Fort Devens. During the last 5 days of August when the troop population was reduced to about 5,000, the average water consumption increased to 195 g.c.d. Actually, however, the number of persons using water during this period was in excess of 5,000. A certain amount of construction was being carried on which required water for both the workers and the construction operations. Furthermore, this 5 day period included a week-end with the usual influx of visitors. Thus, the actual per capita consumption during this period was probably somewhat less than the 195 g.c.d.

It is also seen from Figure 1 that the daily water consumption varies considerably during the week, falling off on Saturdays and Sundays when large numbers of troops are away on furlough,

and reaching a peak on Fridays when preparations are being made for these week-end furloughs. Furthermore, prior to the extended maneuvers in August, a large number of troops were absent* from camp two or three days at a time on short maneuvers. Water consumption data from April to July, inclusive, when the camp population was relatively stable (varying between 26,000 and 28,000) are summarized as follows:

	Rate of Consumption	
	m.g.d.	g.c.d.
Average, excluding Saturdays, Sundays, and holidays	2.54	94.0
Average of maximum daily consumption each week	2.82	104.3
Average daily consumption during maximum 7 day week ending July 26	2.58	92.3
The same, but excluding Saturday and Sunday	2.71	97.0

As explained later, the daily sewage flows followed the same fluctuations as the water consumption, but were invariably lower except in rare instances when sewer manhole covers were removed illicitly to drain off surface water before adequate surface drains were available. During the month of July, 1941, the average water consumption was 2.50 m.g.d. and the average sewage production was 2.37 m.g.d.

Reliable data showing hourly water consumption rates are not available. However, sewage flows as recorded at the sewage treatment plant give an indication of the fluctuations in water consumption for the camp as a whole during the 24 hours of the day. The variation in sewage flow is illustrated in Figure 2 which has been prepared from the flow chart for June 20, 1941, when the total flow was 2.8 mil. gal. It is seen from this chart that a peak rate of 4.6 m.g.d. is reached at about 7 a.m. The flow then decreases to a rate of 2.3 m.g.d. at 11 a.m., rises to another peak following the noonday meal, and then falls off during the early afternoon. At

* The population figures shown in Figure 1 have not been corrected for these absences.

FIG. 2 SEWAGE FLOW CHART
FOR JUNE 20, 1941

3 p.m. the flow commences to rise, reaching a rate of 4 m.g.d. at about 7:30 p.m. The rate then falls off until 9 p.m., increases slightly until 10 p.m., and then recedes gradually until 3 a.m. when it reaches its minimum rate of 1.3 m.g.d. The peak sewage flows and the hours of their occurrence are influenced by storage in the sewerage system and the time of flow from the extreme ends of the system to the sewage treatment plant. For this reason the peak sewage-flow rates (Figure 2) are lower than the peak rates of water consumption and occur 1 to 1½ hours later.

The design of main sewers serving regimental areas was based upon certain assumptions regarding the effect of the rigid daily routine of troops upon sewage flows. Recalling the deficiency of

factual data when the sewers were being designed, flow measurements were made in April, 1941, in two sewers, one serving a so-called regimental area having a troop population of 1,100, and the other serving the camp hospital area having a resident population of 1,570. Weirs were installed in sewer manholes and flow measurements were recorded periodically during 24 hours for each area. The flow measurements for the regimental area are shown in Figure 3 and those for the camp hospital in Figure 4.

Referring to Figure 3, the average sewage flow from the regimental area was 90.5 g.c.d.; the maximum flow, occurring at about 7:20 a.m. was 196 g.c.d.; the minimum flow, occurring between 3 and 4 a.m. was 51 g.c.d. From midnight until about 5 a.m. the flow was close to the minimum rate; between 5 and 6 a.m. the rate increased sharply, and beyond this point the fluctuations conformed well to the daily routine of the troops. In general, each mealtime was preceded and followed by a sharp rise in sewage flow.

Referring to Figure 4, the average flow from the camp hospital was 80.7 g.c.d.; the maximum rate of 148 g.c.d. occurred at about 9 a.m.; the minimum

FIG. 3 VARIATION IN SEWAGE FLOW FOR TYPICAL REGIMENTAL AREA HAVING TROOP POPULATION OF 1100

FIG. 4 VARIATION IN SEWAGE FLOW FOR HOSPITAL AREA HAVING RESIDENT POPULATION OF 1570

rate of 36.5 g.c.d. occurred between 3 and 4 a.m.

A comparison of Figures 3 and 4 shows a higher water consumption and sewage flow in the regimental area than in the camp hospital area. This is explained, in part at least, by differences in the operation of the plumbing fixtures. The barracks in all regimental areas have continuous-flushing trough urinals, whereas there are no such urinals in the hospital buildings. Last winter when troops began to arrive at the cantonment in force it was believed that water consumption rates were excessive. That this apparently high consumption was due to leakage in the distribution system seemed improbable. Following the laying of water mains each line was tested under pressure in accordance with standard practice and was made tight before the trench was backfilled. As soon as the high rates of consumption became known a waste survey was undertaken, with barracks, mess halls, and other buildings inspected both during the day and night. It was found that water faucets were left open in many barracks and other buildings, and that numerous toilet flushometer valves were discharging continuously. Orders were then issued to correct the condition and the necessary adjustments and repairs were made. Measurements of the quantity of water used by the trough-urinals showed an average con-

sumption of approximately 2 gal. per minute per urinal.

Following this survey consideration was given to other methods of urinal flushing, and ultimately a decision was reached to change from continuous to intermittent flushing by the use of flushometer valves. Although this change has not been made as yet, it is probable that the new valves will permit a marked reduction in water consumption and sewage flow wherever the urinals are used.

Referring again to Figures 3 and 4, it should be recalled that the peak sewage flows are influenced by storage in the sewers. Peak rates of water consumption in these areas would be higher than the peak rates of sewage flow. The average rates of water consumption in the two areas also would be higher than the average sewage flows since all of the water consumed does not reach the sewers, particularly that used for washing trucks and for sprinkling newly seeded ground. All of the sewers at Camp Edwards are well above the ground water table and, for the most part, lie in a sand and gravel soil; hence, the sewage flows are practically unaffected by ground water infiltration. While the sewers should be reasonably tight, having been laid with sulfur compound joints, any leakage that might occur would tend to be outward rather than inward.

It is hoped that the water consumption and sewage production data presented in this paper will prove to be helpful to engineers and others concerned with the design of utilities for future cantonments. In using these data, however, it should be borne in mind that there may be important differences in water requirements even for cantonments of the same general character. For example, at Camp Edwards plans called for a post laundry at the time the water and sewerage systems were being designed, but the laundry was never built. Where cantonments have such laundries, water requirements and sewage flows will be measurably higher. Again, ground water conditions on Cape Cod are favorable to the construction and operation of sewers, whereas at other cantonment sites appreciable allowances may have to be made in the design of sewers and sewage treatment works for ground water infiltration. Camp Edwards is built on an almost level terrain, and elevated tank storage gives a relatively uniform static water pressure of approximately 60 lb. per sq. in. Where the terrain lends itself to other forms of storage, pressures may be higher or lower than this amount, either of which condition will affect water consumption rates. Water consumption may also be increased appreciably by refueling at air

fields where the "Aqua" system of gasoline displacement is used. While this was not an important consideration at the Camp Edwards air field, the use of water for this purpose should not be overlooked where large numbers of planes must be refueled. The "Aqua" system used at two moderate sized military air fields in New England requires water for gasoline displacement at the rate of about 350,000 gal. in 4 hr., equivalent to a rate of 2.1 m.g.d.

Probably the most important consideration of all with regard to ultimate requirements of water and sewerage works is the possible expansion of a cantonment. No specific allowance was made for this factor at Camp Edwards, but an ultimate population of 45,000 troops was considered to be a reasonable possibility in view of 1917-1918 experience.

While, officially, no authority was given to provide for such a population this possible degree of expansion was not ignored either in the design of the water works or the sewerage system. The saving grace in the performance of many a municipal water or sewerage works has proved to be the factor of safety given by the allowances used for the future growth of the municipality, a factor of safety which the designer of similar works for an army cantonment cannot safely ignore.

The Relationship of Vocational Rehabilitation to Industrial Hygiene*

DAVID AMATO

Wage and Hour Division, U. S. Department of Labor, Washington, D. C.

I AM very glad to have this opportunity to express some of my personal views on the relationship of vocational rehabilitation to industrial hygiene. As one who has benefited from a federal-state program of vocational rehabilitation, I have good reason to feel that my discussion is not merely theoretical. You will understand that I speak as an individual and that my ideas on this subject are not to be taken as necessarily representing the official policy of the Wage and Hour Division.

SIZE OF THE PROBLEM

Despite preventive measures and methods of treatment devised in recent years, the number who become disabled each year from industrial and non-industrial injuries and disease is enormous. The Division of Vocational Rehabilitation of the U. S. Office of Education reports that 800,000 persons become permanently disabled every year because of congenital defects, accidental injury, and disease. Latest figures of the Bureau of Labor Statistics on industrial injuries in the United States indicate that in 1940 nearly 90,000 persons suffered some permanent impairment and 1,782,000 persons temporary disabilities. The total time lost from these injuries alone, according to the Bureau of Labor

Statistics, was 125,240,000 man-days. The National Safety Council, in its 1941 edition of *Accident Facts*, reports that accidental injuries reached the staggering total of 9,100,000 in 1940.

METHODS OF TREATMENT

Without enumerating the economic costs resulting from this human waste, since it is obvious from the figures just quoted that the total cost would be astronomical, let us see what society has done to cope with this social problem. First, we have stressed preventive programs designed to reduce to a minimum health and safety hazards in industrial as well as non-industrial environments. I hardly need to tell you of the progress that has been made in this regard or stress the importance of prevention. Second, as evidenced by the many clinics and sanatoria for the medical treatment of injuries and diseases, we have recognized a social responsibility for making such services available to wage earners. Largely due to your interest in physical rehabilitation, many employers have recognized the value of an industrial medical and health program. Third, in our efforts to restore disabled workers to normal life, we have attempted, although on a very limited scale, to rehabilitate vocationally physically disabled workers and to restore their earning capacity. Of the three methods of treatment of this

* Read before the Industrial Hygiene Section of the American Public Health Association, at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

problem, vocational rehabilitation has attracted the least attention and its importance has been the least appreciated. Although vocational rehabilitation as a social responsibility has been accepted by all the states, the federal government, and private philanthropic agencies, only about 15,000 physically handicapped persons are vocationally rehabilitated annually by the federal-state program and some 15,000 by philanthropic organizations.

The task of restoring the injured worker to normal life naturally starts with providing him the necessary medical or surgical care. But it should not stop there. Frequently, such a worker may not be able to return to the labor market without undergoing a program of guidance and training designed to restore his former vocational efficiency, or to direct his interests toward other pursuits better adapted to his talents. The total task of rehabilitation is not completed until the patient is again economically self-supporting. Failure to recognize this may be wasteful. The emotional conflict which arises when the individual feels that only a life of dependency stares him in the face may undo the benefits of the medical attention he has received. Physical rehabilitation without vocational rehabilitation is simply unfinished business. And it is often a bad investment.

SALVAGING INDUSTRIAL MAN POWER

Recent increases in the demand for skilled labor, arising out of the defense program, have emphasized the need for action in salvaging much more of this human waste. Reports from England indicate a growing interest in rehabilitation in the Ministries of Labor and Health. Commenting on rehabilitation as a defense measure, the *London Economist* of November 2, 1940, has this to say:

Rehabilitation has been defined as the process of reconditioning which will be required

in certain cases after clinical treatment in order to obtain full restoration of working capacity. It means more than medical recovery; it involves not simply patching up of the injured person at home or at a clinic, but seeing that his ability to work is restored. Its importance is not simply humanitarian. It is economic; and the bringing back of disabled men and women into work with full output and full earnings was never more needed than at this stage of the present conflict of industrial man power.

In 1932, Roy Anderson undertook a study of the placements made by the Employment Center for the Handicapped in New York City. In his book, *The Disabled Man and His Vocational Adjustment*, published by the Institute for the Crippled and Disabled, Mr. Anderson used 4,404 cases of men with various orthopedic disabilities, all of whom were placed without being vocationally rehabilitated. This study revealed the tendency on the part of those who held jobs in the skilled and semi-skilled groups before disablement to drop down the scale into work of an unskilled nature. Specifically, 25 per cent had been skilled and 23 per cent had been semi-skilled workers before disablement. After disablement, only 6 per cent held skilled and 12 per cent semi-skilled jobs. This situation is wasteful of skill and training under any conditions; under present circumstances, with certain skills at a premium, it is tragic, not only from the viewpoint of the disabled worker but from that of the public interest. And the waste is increasing, for the Bureau of Labor Statistics reports that in each of three vital defense industries—machine tools, aircraft production, and shipbuilding—the number of disabling injuries per million hours worked increased by about 22 per cent in 1940 over 1939.

ECONOMIC AND SOCIAL BENEFITS OF VOCATIONAL REHABILITATION

Every successful effort toward vocational rehabilitation and placement of handicapped workers can be justified

on the basis of dollars and cents without recourse to sentimentality. The cost of supporting a disabled adult in idleness is generally estimated to be upward of \$500 a year, whereas a single expenditure averaging \$300 or less could have made him self-supporting. Thus, besides eliminating the high cost of institutional and private care, the vocational rehabilitation of the handicapped would add millions of dollars to the national income. The Division of Vocational Rehabilitation of the U. S. Office of Education, which coöperates with all of the State Vocational Rehabilitation Bureaus, estimates on the basis of experience over the last 20 years that the average earnings of a disabled worker after rehabilitation is about \$1,000 a year. Multiply this figure by 150,000 (the number rehabilitated by the federal-state program since 1920) and the combined earnings of such workers represent an annual income of about \$150,000,000. And while adding \$150,000,000 to the nation's income, we have saved \$75,000,000 which otherwise would have been spent for the care of these people.

Various studies have indicated the wide variety of useful occupations in which disabled workers may be trained advantageously. One made by the Division of Vocational Rehabilitation lists 628 different types of jobs held by physically handicapped persons. Because of the scientific treatment of the training and placement problems of the handicapped worker, it is not surprising to find that he is often more successful than the able-bodied. He is trained and placed in a job where he is happy and where his disability will interfere least with the performance of the duties required.

VOCATIONAL REHABILITATION AS A PART OF THE INDUSTRIAL HEALTH PROGRAM

At the Special Conference of State and Territorial Health Officers with the

U. S. Public Health Service on September 16, 1940, Dr. Paul A. Neal of the Division of Industrial Hygiene, National Institute of Health, outlined a specific program of industrial hygiene in which he listed also the necessity for a "determination of methods for the absorption of handicapped persons into vital industries for national defense." Although Dr. Neal did not indicate how this would be accomplished, it is obvious that, in order to qualify, many of these workers will have to be vocationally rehabilitated. One of the ways this may be done is to include vocational rehabilitation as part of an industrial health program. Since many employers already have acknowledged their interest and responsibility in physical rehabilitation, and since physical rehabilitation without vocational rehabilitation is unfinished business, it follows logically that such employers should wish to participate in the vocational rehabilitation of their disabled workers as a part of their medical and health programs.

Because of the medical and work records it accumulates, an industrial medical unit would appear to be in an excellent position to plan and effectuate the training and placement of physically handicapped workers. A survey of each job in the establishment would determine, among other things, the physical requirements of each job. Such data, together with the medical diagnosis and prognosis and an appraisal of the worker's abilities, capacities, interests, and occupational history, would serve as a basis for charting the program. Possibly one of the best advantages of such a program in industry is that the resulting coöperation between the medical and personnel units would facilitate the training and placement of disabled workers with the least possible delay. This in turn would reduce the conflict which so often disorganizes the personality and would assure success in the total task of restoring the individual to

his independent place in society. Such a program would certainly eliminate to a large degree the fear of dependency and insecurity that is in the minds not merely of the handicapped but of all workers.

An employer primarily interested in the efficient operation of his plant surely should want to know something about the general performance of handicapped workers and what to expect so far as accidents are concerned. Fortunately, there is a considerable body of data to satisfy any employer's interest. The actual performance of such workers as compared to non-handicapped employees has been shown to be very favorable. In 1932, the Western Electric Company of Kearny, N. J., made a comparison of about 652 disabled workers with a similar group of non-handicapped employees doing the same types of work. Resignations, absences due to sickness, and discharges for cause were found to be from 7 to 8 per cent higher among the non-handicapped than among the disabled, and there were 5.6 per cent fewer accidents among disabled workers.

Employers are frequently reluctant to employ handicapped workers because of the fear of having to pay a higher compensation rate. These fears have no basis. The initial compensation rate generally is fixed for the industry as a whole and the total cost is based on the number of employees, occupations, and pay roll. No information is generally required regarding the physical condition of the employees. The rate is later adjusted on the basis of the plant's experience. The claim that the experience must necessarily be poor if handicapped persons are employed has not been substantiated. The Ford Motor Company, as an example to show that the contrary is generally true, employs more than 10,000 physically handicapped workers and reports that it has the lowest compensation insurance rate in the automotive industry. Since in an

industrial vocational rehabilitation program the placement and training of such workers would be based on the physical requirements of each job, the accident risk could be reduced to a minimum.

J. W. Dietz, author of the article entitled "An Experiment with Vocationally Handicapped Workers" which appeared in the February, 1932, issue of the *Personnel Journal*, made the following conclusion regarding the Western Electric Company's experiment:

Based upon the data presented thus far in this paper, we are of the opinion that there is no real reason why people possessing certain vocational defects should not be employed by large industrial concerns. The results of our year's experience with vocationally handicapped workers were sufficiently satisfactory to make their acceptance a part of the standard practice of our Medical Department.

Likewise, as a result of our experience gained in working with the vocationally handicapped employees, significant changes took place in our thinking regarding other phases of our rehabilitation problem.

It occurred to us that we had not exercised the same care in providing an adequate placement and follow-up routine for employees who were impaired with sickness or injury while in the employ of the company.

A follow-up and placement program can be effectuated with the least possible cost and with the maximum advantage to employers and disabled workers alike. Although the services of a rehabilitation consultant would be valuable and justified in the larger establishments, a close coöperation between the medical and the personnel departments could obviate the appointment of rehabilitation specialists in most concerns that would establish and carry out this program. In either case, after a worker had been physically rehabilitated, the medical and work records would be available to the personnel interviewer in the guidance and placement of the worker. Essential to this program is the coöperation possible with private and public vocational rehabilitation agencies whose accumulated

knowledge and experience would be invaluable.

The Division of Industrial Hygiene of the National Institute of Health and the State Industrial Hygiene Agencies might well formulate a skeleton outline showing the place and functions of vocational rehabilitation in an industrial health program. Additional research could profitably be conducted as to methods and measures for meeting the particular needs of employers.

CONCLUSION

I am frequently asked, "If vocational rehabilitation is as practical as you say it is, why hasn't it been more widely appreciated?" There are many answers to that question. I have tried in my discussion of the relationship of vocational rehabilitation to industrial hygiene to give one answer. Perhaps the greatest handicap to progress has been

that we have permitted our sentiment to run away with our reason. We have been inclined to overlook the fact that, once the physical disability has been treated, the central problem is that of restoring earning capacity so the handicapped persons may become self-supporting. Since the return of such a worker to the labor market should be the ultimate goal, we must recognize our work as unfinished when it stops short of that. We must show employers that it is to their economic advantage to complete the job. We must impress upon them the fact that they have developed equities in workers who become disabled, and, as in the case of a machine, they will profit when they repair the worker rather than discard him. If we succeed, we will have done much to make social and economic assets out of many present human liabilities.

The Public Health Engineer in the Emergency*

A. GRANT FLEMING, M.C., M.D., D.P.H., F.A.P.H.A.

*Strathcona Professor of Public Health and Preventive Medicine, McGill University,
and Medical Director, The Bell Telephone Company of Canada,
Montreal, Canada*

HEALTH is at all times of major importance to the individual and to the nation of which he is a part. In the event of a national emergency, fitness, both physical and mental, becomes of paramount importance, because it is man power that determines the capacity of the nation to produce weapons of freedom and to use these weapons.

Health, from the personal or individual point of view, is a condition of well-being that determines capacity to work, to play, to be happy and useful. As the nation is made up of individuals, it is obviously true that in order to raise the standards of national health, we must promote individual physical and mental health.

Public health, though a comparatively new art, has passed through several well-marked phases of development. Public health is practical in its outlook. "The greatest good for the greatest number" is an axiom that cannot be lost sight of when determining the best use of public health funds and personnel.

At any particular period, the scope of the public health program is limited by the knowledge which has been made

available concerning the prevention of disease and the promotion of health. In fact, it may be said that the real purpose of public health is to bridge the gap which exists between knowledge and practice, and so minimize the loss of productive lives and capacities.

Public health as we know it today developed as part of a general movement for social reform, the aim of which was to correct some of the unfortunate results of industrialization. The public health pioneers saw disease, poverty, and filth going hand in hand. The emergency they faced grew out of the industrial revolution when the new factory workers came to live in the industrial centers which sprang up and which were entirely lacking in sanitary facilities.

The public health reformers sought to lighten the burden that was crushing the people, through the institution of sanitary measures which they believed would prevent many of the prevalent diseases. Their chief error lay in the belief, universal at that time, that disease breeds in filth instead of being carried in filth. They did not appreciate the actual and potential dangers in the excretions and secretions of the human or animal body. Nevertheless, through their energetic efforts, much was accomplished.

Following upon the epoch making dis-

* Read before the Conference of Municipal Public Health Engineers, at Atlantic City, N. J., October 13, 1941, during the Seventieth Annual Meeting of the American Public Health Association.

coveries of Pasteur and his coworkers, attention was focused on the control of the communicable diseases. Spectacular progress has been made in the control of many of these, notably those which are spread chiefly by water, milk and food, and by insects. It has been with those communicable diseases, the spread of which is direct from man to man, that the results have in general been disappointing unless active immunization has been possible. Despite the progress which has been made, sickness remains as the major hazard for the masses of the people, including the industrial wage earners.

With the relative control of many of the major epidemic diseases, such epidemics have ceased to be the chief concern of public health. Attention has been gradually directed toward the improvement of health as distinct from the prevention of disease. This required the spread of health knowledge to the general public in such a manner as to bring about the practice of this knowledge by the people as an integral part of their everyday living.

In the enthusiasm for health education and the solution of the health problems of the individual, there was for a time, in many places at least, a tendency to discount the importance of environmental conditions as fundamental to all health work, and to overlook the need for making it reasonably possible for people to practise what they were being taught, through the provision of sanitary facilities.

It might be said that public health is interested in every phase of individual and national life because every phase has some influence on health. Undoubtedly, the greatest public health problem is poverty. Together with poverty, we find ignorance, undernutrition, high morbidity and mortality rates. It is not, however, our problem as public health workers to deal with poverty as such.

In making the decision as to where our responsibility lies, we must avoid falling into the error of thinking that just because we know how to do a certain thing, it is necessarily done. For many years, we have known that milk supplies can be made safe through inspection plus pasteurization. In spite of this, much raw milk is still being sold, and the supervision of many dairy farms and pasteurization plants is still inadequate.

Another error to be avoided is the presumption that because water supplies in most of the larger centers of population are now safeguarded, the same must be true of the smaller towns and rural areas.

The emphasis of the public health program will vary from area to area, depending upon such factors as population, climate, economic conditions, and so on. There is no one standard program which will best meet the needs of all areas. The general purpose is always the same: the prevention of preventable diseases and the improvement of physical and mental health, leading to increased years of health and happiness.

There are certain basic public health requirements, provision for which must be made in all areas at all times. It is the means for providing these services which will vary from place to place and from time to time. Everyone should have available for use safe water, safe milk, facilities for personal cleanliness and for the storage of perishable foods, to mention but a few items which come readily to mind.

With what I have said for a background, we come to face the present-day emergency. We find ourselves living in an armed camp either preparing for or actually engaged in a struggle to preserve everything which we believe makes life worth while.

Under such circumstances, we are challenged, as individual citizens and as

members of public health organizations, to make our most effective contribution toward the national effort to meet the emergency.

I need hardly remind this group that public health includes in its personnel men and women with various professional basic trainings. From each it is expected that he or she will bring to his or her public health duties a capacity to apply technical knowledge to the solution of public health problems. The public health engineer, by reason of his professional training in engineering, is the staff member who is expected to give leadership in the designing, construction, or operation of those facilities which come under the general heading of environmental aspects of disease prevention and health promotion.

The value of the public health engineer, or indeed of any member of the public health organization, lies not only in his professional ability but also in his capacity for and his willingness to become a member of a team which will work in harmony, having the public health as objective. I emphasize this latter point because at a time when the emergency gives rise to many problems of jurisdiction and other irritants, it requires more than a fair degree of the coöperative spirit to avoid friction and not to lose sight of the common objective.

The state of emergency has brought about many changes of public health significance, creating problems but, at the same time, offering opportunities to advance public health.

Shifts of population with the setting up of military camps and defense industries in new areas, or the sudden expansion of population in small centers cannot take place safely without the safeguards which public health, largely through public health engineering, has to offer.

The public health engineer—and I am using that term to include the sanitary

engineer—does not approach his problems alone. He is associated with the bacteriologist and the epidemiologist, for example, in many matters, but, nevertheless, it is upon his shoulders that the major responsibility for environmental conditions must rest.

In the present emergency, public health engineering, as a part of public health, has to consider three major questions: (1) What shall be our attitude toward the maintenance and further development of public health departments? (2) How can we best provide the necessary services for the new defense industries? (3) How can we assist in the provision of essential services for the armed forces?

In most public health matters, a line cannot be drawn between the civil population and the military forces. You will recall how, in 1918 and 1919, influenza swept around the world, sparing neither armies nor neutral nations remote from the war zone.

To whatever extent preventable diseases are allowed to persist and to whatever extent we fail to raise health standards, to a corresponding degree we decrease our ability to meet the emergency.

Man power is, of necessity, the most important national resource available to us in our efforts to deal with the problems arising out of the emergency, from both the military and the civil points of view. Quality of man power depends upon the fitness of the individual, whether in the armed forces, the factory, the farm, or the home.

It is obvious then that not only must there be no slackening in the work of public health departments, but on the contrary, there must be a raising of standards and above all the extension of services to local areas which up to the present have not enjoyed the advantages of adequate public health services.

The effectiveness of a health depart-

ment depends upon two things: the quality of its staff and the adequacy of its budget. No health department can function properly unless it has the leadership, guidance, and services of a qualified public health engineer working in close coöperation with the medical officer of health.

I would say then that the first duty of the public health engineer in the emergency is to do his part as an individual public health worker and as a member of that specialty in public health to promote, develop, expand, and maintain public health engineering services in the official health department organizations.

I do not think that this point can be over-stressed. There is, undoubtedly, going to be serious difficulty in maintaining health department services. There is the natural danger that, under the circumstances, other things may seem to be of relatively more importance. Staff will be lost and difficult to replace. There may develop a tendency to reduce expenditures on public health in favor of what will appear to be more urgent needs.

The responsibility therefore falls upon all public health workers to interpret to the public and to the responsible authorities what the public health departments mean to the nation in the emergency.

It is from the civil population that the armed forces recruit their men; it is from the civil population that defense industries draw their staffs. Thus, it is the health conditions of the civil population which determine the quality of man power available to the armed forces and to industry.

It might be said in all truth that in order to safeguard the health of the armed forces, we must have well organized public health services throughout the whole country. The soldier, sailor, or airman does not stay put. He spends much of his spare time and all of his

leave outside of the militarily controlled area. He eats and drinks in any and every sort of public eating place. Unless these resorts are safeguarded by the health departments, they obviously endanger not only the civil population but also the man in uniform, for the germs of disease do not hold the uniform in awe.

All this brings me to repeat what I said before, namely, that the emergency demands that we press forward in the organization of adequate public health services, particularly for the rural areas, and that we do our utmost to maintain and improve the efficiency of existing services.

A special problem for the public health engineer arises out of the setting up of large and small defense industrial plants in new and sometimes relatively remote areas.

The public health engineer should be consulted as to the selection of sites, and the proper time to consider the question is before the final selection is made. We all know of construction having been started, indeed sometimes finished, before consideration was given to the accessibility of adequate water supplies.

Military necessity may require, at times, the selection of a relatively unfavorable site from the public health point of view, and under such circumstances, the public health engineer must make the best of conditions.

The actual situation in defense industries varies a great deal from place to place. Some plants will be located in comparatively isolated areas with large staffs; in others, the staff will be relatively small. Some plants will be entirely new; others will be an expansion of existing work. The latter are more frequently located in cities or small towns.

Obviously, the public health engineer must be informed as to the nature of the plant, the number of employees,

and so forth, if his part of the planning is to meet the environmental health needs of the situation. Here and in other matters, secrecy is often essential, which means that all must learn to exercise control over their tongues when it happens that, through our work, certain information regarding defense industries comes into our possession.

The industrial defense plants have the same requirements as all other industrial plants with regard to water supplies, sewage disposal, facilities for personal cleanliness, lunchrooms, kitchens, and food storage, as well as adequate provision for lighting and ventilation, and, depending upon the nature of the industry, special protection in connection with dust, fumes, explosives, and so on.

In the isolated plants, sleeping and recreational accommodation may be required, and these for both sexes. In this particular, it is well to keep in mind the importance of the maintenance of morale in which environmental conditions play an outstanding part. If, for example, the plant is one which operates twenty-four hours a day, the fact must not be overlooked that the night workers require quiet sleeping quarters during the day.

Perhaps the most difficult health situation arises in the sudden expansion of an industry located in a small town which lacks satisfactory community sanitary facilities. In such cases, with regard to sanitation, the town itself with its inhabitants cannot be divorced from the plant with its employees. What is needed, under such circumstances, is a joint effort to secure safe and adequate sanitary facilities for both the town and the industry. Under these conditions, overcrowding in dwellings is a particularly difficult situation to meet promptly and satisfactorily, but to neglect doing so will almost surely give rise to an unhappy health situation.

The public health engineer, either as a member of the armed forces or acting

in his civil capacity, should be consulted in the selection of new military camps and the expansion of existing camps.

The attitude of the responsible military authorities toward military training has changed a great deal. The old idea of "hardening" men through needless exposure to cold and wet is now in the discard. In its place has come at least a partial acceptance of the more modern views with regard to education and health.

Perhaps it is the development of mechanized warfare which has emphasized skills rather than strength. Mechanized warfare calls for long periods of training which means that the man, when trained, is particularly valuable and difficult to replace. Safeguarding the health of these men while in training and afterward is highly important to the army, the navy, and the air force.

I mention this change because it means that the public health engineer, in planning for a military camp today, does not merely consider accommodation for eating and sleeping. He must bear in mind that the modern military camp has to a considerable extent become a school which needs classrooms, laboratories, and practise rooms. This demands consideration of lighting, ventilation, and all the other special environmental needs of a school.

I should like to mention also the necessity of keeping in mind provision for expansion, because it seems as though military camps never attain their full growth. Having made adequate provision for the twenty thousand men who were to be accommodated, it is often found that thirty thousand are expected to move in shortly.

From what I have said, it is clear that the public health engineer has an important rôle to play in the emergency. His services are essential to the civil, industrial, and military populations, and this, in effect, means the whole population. The important point in all

this is to make certain that the public health engineering personnel is so distributed as to make the services of the engineer available where and when needed. If this is done, we may rest assured that the contribution of the

public health engineer to defense will meet the needs, and will assure the country of the full advantages in public health which this important member of the public health organization can offer to his country in its emergency.

Results of Serologic Tests for Syphilis in Non-syphilitic Persons Inoculated with Malaria*

L. E. BURNEY, M.D., J. R. S. MAYS, M. D., AND
ALBERT P. ISKRANT

*Passed Assistant Surgeon, U. S. Public Health Service, Kansas City, Mo.;
Milledgeville State Hospital, Milledgeville, Ga.; and Assistant Statistician, U. S. Public Health Service, Washington, D. C.*

THE influence of malaria in producing positive serologic tests for syphilis in patients not infected with this disease has been a controversial question for many years. This problem is of more than academic interest. There is a large malarial region in this country. Those states affected have a large Negro population among whom there is a high prevalence of syphilis. Here, as elsewhere, the diagnosis of syphilis has rested largely upon the serologic test. Therefore, if malaria may produce positive tests in persons who do not have syphilis, it is essential that we know this to prevent false diagnoses and unnecessary therapy.

REVIEW OF THE LITERATURE

Much has been written concerning the effect of malaria on the sero-diagnosis of syphilis. There is approximately equal division among these reports as to whether malaria actually has any effect. The literature, up to 1938, has

been well reviewed by Hazen and his associates.¹ Only a few of the more important observations will be mentioned here.

Lloyd and Mitra² report on 85 cases of malaria in a hospital of Calcutta, 14 per cent of whom had presumably positive reactions for syphilis. They state that this falls within the expected syphilis rate of their hospital population and conclude, therefore, that there is little evidence that malaria causes nonspecific positive reactions when modern technics are used. Kolmer,³ from his observations and experience, states that malaria has no influence upon serologic reactions, although mentioning that sera from any acute febrile disease may become more anti-complementary than usual. His belief is that errors in technic probably account for reported cases of nonspecificity. These statements were reaffirmed in a subsequent paper,⁴ adding that "The occurrence of positive reactions in malaria is presumptive evidence of syphilis."

Saunders and Turner,⁵ working with a population in which yaws was prevalent, malaria present, and syphilis rare, found that the percentage of positive reactions was no greater among malarial

* Read at a Joint Session of the Laboratory and Epidemiology Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

Experiment conducted in the Department of Psychiatric Research, Milledgeville State Hospital, Milledgeville, Ga.

patients than among the general population. They did suggest, however, that acute malaria may act as a provocative agent in raising a low titer reagin to the complement-fixation threshold. Similarly, Canova⁹ concluded from his observations that malaria merely reactivates an old syphilitic process and brings out latent and serologically negative syphilitic infections.

Fisher and Ginsberger,⁶ Taussig and Orgel,⁷ and Wilson and Levin⁸ made contrary observations, namely, that malaria may produce nonspecific positive serologic results. Cumming and his coworkers,¹⁰ in a study of 36 cases of presumably non-syphilitic patients with malaria, found a significant percentage of false positive reactions, varying from a low of 11.1 by Hinton to a high of 19.4 by Kolmer. Hazen and his associates reported 8 per cent positive reactions in a study of 266 presumably non-syphilitic white persons with malaria. Stryjecki¹¹ found in his study of patients with malaria, that 40 per cent gave a false positive reaction for syphilis, although this reaction was transitory.

Several aspects of the papers cited in the preceding review are to be particularly noted. First, and most important, is that none of these observations are really controlled studies, in that they were made either on routine hospital patients or patients in the field in whom syphilis could not be ruled out in all cases. Comparisons of rates were made with the general population. Most of the observations were made using a modified Wassermann technic at a time when the sensitivity of tests was not so high as it is today and the technics were not so well standardized. Finally, in none of the preceding studies were serial tests carried out on the same patient at intervals throughout the course of the infection. The conclusions were usually based on single specimens taken at varying periods in the course of the disease.

The first systematic and controlled study of this problem was made by Kitchen and his coworkers¹² who inoculated non-syphilitic patients suffering from functional psychoses with malaria, using similar patients not inoculated with malaria as controls. Using a complement-fixation and a Kahn test, they found that every case which developed malaria exhibited positive results at some time during the course of the infection. This formed the most conclusive evidence yet presented on the effect of malaria in producing a positive complement-fixation or flocculation test in non-syphilitic patients.

Our efforts have been directed toward further clarification of this apparently confusing problem. The primary purpose of this study was to determine the influence of malaria on the complement-fixation and flocculation tests for syphilis. Secondary considerations were: (a) influence of the stage of the disease, (b) to observe any differences in the several tests used, (c) to determine the effect of duration of the disease, (d) to learn if the number of malarial parasites in the blood or the temperature at the time of withdrawal had any effect on the results, and, finally, (e) to determine the period of maximum titer of the serum as demonstrated by the Kahn quantitative test.

METHODS

The laboratories of Eagle, Hinton, Kahn, Kline, and Kolmer kindly agreed to perform the tests bearing those names on all specimens collected in the course of this study. In addition, the Venereal Disease Research Laboratory of the U. S. Public Health Service, under the direction of Sr. Surgeon J. F. Mahoney, also participated, performing the Kahn, Kline, and Kolmer tests on all specimens.

Eleven patients with functional psychoses were inoculated with malaria. Syphilis was excluded by means of history physical examination, two negative

TABLE 1
Serologic Pre-testing Results

<i>Type of Test</i>	<i>Number Positive</i>	<i>Number Doubtful</i>	<i>Number Negative</i>
Eagle Wassermann	0	0	11
Eagle Microflocculation	0	0	11
Hinton	0	1	10
Kahn Standard (Kahn)	0	0	11
Kahn Standard (Mahoney)	0	0	11

Kline Diagnostic (Mahoney)	0	0	11
Kolmer (Kolmer)	0	0	11
Kolmer (Mahoney)	0	1	10

One case had two doubtful reactions to the Hinton test and one case one doubtful reaction to the Kolmer (Mahoney) prior to inoculation. These cases, both of which had positive reactions during the malarial course, were not included in the figures for such tests.

blood serologic tests and one negative spinal fluid. All pre-inoculation specimens were submitted to the above serologists. In addition, 4 controls were selected, 2 with syphilis and 2 without.

Three patients were inoculated with 10 ml. of blood containing *Plasmodium vivax*. The other 8 patients were infected directly by the bite of an infected mosquito. The blood containing the parasites and the infected mosquitoes were obtained from Dr. Martin Young of the Public Health Service Malaria Laboratory at Columbia, S. C. The infected blood was obtained from functional psychotics with malaria who did not have syphilis as proved by negative history, physical examination, and blood and spinal fluid serologic reactions.

There is no evidence that the mosquito may transmit the spirochete of syphilis. Therefore, we can reasonably state that

our patients were inoculated only with *Plasmodium vivax*. The only observed difference between the two methods of inoculation was the longer incubation period where the bite of the infected mosquito was used.

Enough blood was withdrawn from each patient to send a comparable amount to each laboratory in the form of whole blood. This was sent airmail to the participating serologists on the same day as withdrawn and under a code number. Besides the two pre-inoculation specimens, blood was collected once a week during the incubation period, every 4 days during the active stage of the malaria, and again once a week after termination of the disease by the use of quinine, until the serologic reaction became negative. Quinine was given when the patient had had 10 paroxysms. A total of 13 specimens

TABLE 2
Number of Persons Having Positive Reactions by Different Tests

<i>Type of Test</i>	<i>Number Positive</i>	<i>Number Doubtful</i>	<i>Number Negative</i>

Kline Diagnostic (Mahoney)	9	1	1
Kolmer (Kolmer)	7	0	4
Kolmer (Mahoney)	9	1	0

was obtained when some of the patients were at the height of a paroxysm. Parasite counts were made by the Malaria Laboratory of the U. S. Public Health Service at Savannah, Ga.

OBSERVATIONS AND DATA

Table 1 presents the serologic results before inoculation with malaria.

All cases had at least one positive reaction to the Kahn Standard (Kahn), the Kahn Standard (Mahoney), and the Kline Diagnostic (Kline), during or after the malarial attack. The number of persons having positive reactions to the other tests is shown in Table 2.

No positive or doubtful reactions were reported on the negative controls by any of these tests during this period. In cases that were positive, the positive reaction was never an isolated one. Invariably another positive or doubtful reaction was returned on the same case to that particular test. In none of these tests was there a single instance of a negative occurring between the first and last positive reactions, and in only one case (Kolmer-Mahoney) did a doubtful occur during this interval.

Table 3 presents the total positive reactions after inoculation with malaria.

The results of the various tests in the different stages of malarial activity are shown in Table 4. The febrile stage was delimited by the first and last elevations

of temperature to 37.8° C. or 100.0° F. In this table a doubtful reaction was considered as positive if, at the beginning of the stage of positivity, it was followed by a positive blood, or if, at the end of the stage of positivity, it was preceded by a positive blood. One patient had a positive reaction to the blood withdrawn on the day on which first parasites were evident, which was the day before the first paroxysm. With this one exception, no positive reactions were observed prior to fever.

Although the percentage of positive reactions within each stage varied between different tests, in general they all showed the same tendency. During the first week of fever, it varied from 5 per cent in the Eagle Wassermann to 52 per cent in the Kahn Standard (Mahoney). Without exception the percentage of positive reactions in the second week of fever was higher than for the corresponding test for the first week of fever. Again the Eagle Wassermann had the lowest percentage (23) and the Kahn Standard (Mahoney) the highest (87). Only 3 patients had a fever of over 2 weeks' duration and only 4 samples of blood were withdrawn in the 3rd week of fever. The percentage of positive reactions declined after the termination of fever. Only 2 out of 20 samples of blood withdrawn more than 3 weeks after termination of fever were not nega-

Kolmer (Kolmer)	12-20	7-10	6-11
Kolmer (Mahoney)	18-26	6-8	10-15
Hinton (Hinton)		No Positives Reported	

The two sets of figures represent the minimum and maximum durations. One figure is based on the first and last recorded positive blood, the other on the last negative prior to the period of positivity, and the first negative after this period. The difference represents the time between tests in which the blood reaction is unknown.

ginning of the stage of positivity, it was followed by a positive blood or if, at the end of the stage of positivity, it was preceded by positive blood. Figures for the average known and possible durations of positivity for each type of test are given.

In Table 6 are the corresponding figures for the longest number of days of positivity. With the exception of the Kahn Standard (Mahoney) and Kolmer (Mahoney) on the same patient, no known duration of positivity extended over a period longer than 4 weeks.

The longest duration of febrile activity was 18 days and the shortest 7, with an average of 13 days. There was

no apparent relationship between the duration of clinical activity and of positivity, nor was there any evidence that the longer duration of positivity was always associated with its onset early in the malarial stage. The only definite finding was that the patients with the longest durations of positivity remained positive for the longest periods after the administration of quinine. In Chart I the percentage of positive reactions to the Kahn Standard (Kahn) is plotted by time-period after appearance of parasites. It increases to the maximum of 88 in the 3rd week after the first parasites, and then declines, all cases being negative by the 7th week.

TABLE 6
Duration of Positivity

Kolmer (Kolmer)	19	40
Kolmer (Mahoney)	36	44

CHART I

Percentage of Positive Reactions and Composite Titer of the Kahn Standard Test for Syphilis in Nonsyphilitic Persons Inoculated with Malaria by Time Period After Appearance of Parasites.

The height of the peak temperature could not be shown to influence either the duration of positivity or the number of technics giving a positive result. Three cases positive to all tests except the Hinton had peak temperatures of 106.4°, 105.0°, and 106.2° F. Four cases never positive to four tests each had peak temperatures of 105.6°, 106.2°, 105.0°, and 106.4° F.

Consideration was given to the time-period from inoculation to appearance of parasites and its possible relation to the positivity of the blood. It was found that the 3 cases with the longest intervals remained seropositive for longer than the average period. Conversely, the 3 cases with shortest time-period between inoculation and the appearance of parasites remained seropositive for less than the average period. It is seen in Table 5 that on the average the Eagle Wassermann had the longest duration from the first appearance of parasites to the first positive blood.

The reactions to the various tests were studied at the time most tests showed positive, that is, at the time of maximum positivity on the basis of all the tests.

In general, technics giving a positive reaction on a given case tended to do so at the same time. With the exception of the Eagle Wassermann, all the technics which were ever positive for a particular patient were positive simultaneously on at least one sample of

blood. The number of days from the first appearance of parasites to maximum positivity of the blood on the basis of all tests varied from 7 to 24 days, with an average of 15. In 6 cases this maximum positivity occurred after the last paroxysm, and in 3 after the start of quinine. In one patient the period was 11 days and in another 12 days after start of quinine.

An analysis of the titer of the Kahn Standard test shows that the occurrence of the maximum titer varied from 4 to 20 days after the first appearance of parasites, with a mean of 11 days. In Chart I the composite titer is plotted against time elapsed after the first appearance of parasites. This composite, which was obtained by adding all titers for all tests made in a particular period, counting negatives as zero and dividing by the number of tests made, reaches a peak of 22 in the second week after the appearance of parasites. The highest individual titer observed was 120. In 8 out of 11 cases studied, the highest titer appeared within 2 weeks after the first appearance of parasites, and in 10 cases in either the first or second positive reaction recorded.

Of 13 samples of blood withdrawn at the peaks of paroxysms, one titer of 120, one of 4, one of 3, two of 2, and eight of 0 were obtained. The titer of 120 was on blood withdrawn in the second week of fever.

There was no demonstrable correla-

TABLE 7

Agreement Between Tests at Time Most Tests Were Positive

Type of Test	Positive	Doubtful	Negative	Not Done
Eagle Wassermann	4	1	3	3
Eagle Microflocculation	3	2	3	3
Hinton	0	0	6	4
Kahn Standard (Kahn)	11	0	0	0
Kahn Standard (Mahoney)	10	0	0	1
Kline Diagnostic (Kline)	11	0	0	0
Kline Diagnostic (Mahoney)	7	1	1	2
Kolmer (Kolmer)	8	0	3	0
Kolmer (Mahoney)	9	0	0	2

tion between the parasite count and positivity of the blood. Six of the 11 cases attained maximum positivity on the basis of all tests after the last paroxysm and 3 after the start of quinine. One case attained maximum positivity 11 days, another 12 days after start of quinine.

Spinal fluid tests were performed on 3 patients while some of the blood tests were positive. All results were negative with the exception of a doubtful Kahn Standard and a 3+ Kahn presumptive as performed by Kahn on one specimen. The globulin and colloidal gold were negative and the protein 28. The Hinton, Kline Diagnostic (Kline), Kline Exclusion (Kline), Kolmer (Kolmer), and Kolmer (Mahoney) were negative on the same sample of fluid.

DISCUSSION

There can be little doubt that malaria does exert a pronounced influence upon the specificity of the complement-fixation and flocculation tests. In this series of 11 dementia praecox patients inoculated with malaria, all gave false positive reactions by at least two different techniques. The Hinton test was the only one which failed to give at least one positive reaction. This is difficult to understand in view of previous studies^{10, 1} in which false positive reactions were obtained with the Hinton test in 11.1 and 4.4 per cent of patients with malaria.

Syphilis was excluded as a cause of the positive reactions in this study by the negative blood and spinal fluid serologic reactions, history, and physical examination before inoculation with malaria, and by the further fact that all patients became and remained seronegative after complete recovery from malaria. This is in contradiction to the claims of many previous authors who state where positive reactions were obtained in patients with malaria, there was concomitant syphilis. Their failure to detect this false positivity may have

been due to a variety of reasons, chief among which were probably low sensitivity of the serologic tests and failure to take an adequate number of specimens over a sufficiently long period of time. Certainly, the agreement of these findings with those of Kitchen and his associates presents strong evidence that malaria does produce a positive complement-fixation and flocculation reaction in patients who do not have syphilis.

The public health significance of this observation is self-evident. There is a large area in this country in which malaria is endemic. If we are to prevent erroneous diagnoses in asymptomatic syphilis in this area, the influence of malaria on serologic tests must be considered in each individual patient. The observation that the reaction may be positive several weeks after the cessation of clinical malaria adds to the problem. Certainly a serologic test for syphilis in a patient with active malaria, or one who has had malaria within a period of 4 weeks, should not be used as a basis for diagnosis in the absence of history and physical findings of syphilis. Rather, one should wait until at least 4 weeks have elapsed since the termination of the malaria, and then repeat the serologic test at least twice before using this as a basis for the diagnosis of asymptomatic syphilis without history.

SUMMARY

Of 11 apparently non-syphilitic dementia praecox patients inoculated with malaria, all cases had at least one positive reaction to the Kahn Standard (Kahn), the Kahn Standard (Mahoney), and the Kline Diagnostic (Kline). Out of 11 cases, positives were returned on 9 according to the Kline Diagnostic (Mahoney); 1 case returned three doubtfuls; and 1 case was never positive or doubtful. Out of 10 cases, the Kolmer Complement-Fixation test (Mahoney) was positive on 9, and the other patient had one doubtful reaction.

However, out of 11 cases, only 7 were positive to the Kolmer Complement-Fixation (Kolmer), and 4 cases were never positive. Five cases were positive out of 11 according to the Eagle Wassermann, and of the 6 that were never positive, 1 had a doubtful reaction. Only 4 patients out of 11 tested according to the Eagle microfloculation test were positive, and 1 of the other 7 had two doubtful reactions. However, this result of 4 patients positive out of 11 is statistically significant when it is known that all 11 were negative before inoculation. None of the 10 patients were positive to the Hinton test (Hinton), but 3 of them showed one doubtful reaction. No positives or doubtfuls were returned on any of the negative controls by any of these tests during this period. It may also be remarked that in those cases which were positive, the positive test was never an isolated one. Invariably another positive or doubtful reaction was returned on the same patient.

In none of these tests is there a single instance of a negative occurring between the first and last positives, and in only 1 case does a doubtful occur during this interval.

The greatest proportion of positive reactions occurred 15 to 21 days after the onset of clinical activity. With the exception of the Kahn Standard (Mahoney) and the Kolmer test (Mahoney) on the same patient, in no patient did the positivity to any test extend over a period longer than 4 weeks.

The duration of clinical activity, highest temperature reached, time of withdrawal of blood in relation to an individual paroxysm, or density of para-

sites, did not demonstrably influence the serologic reactivity of the blood. Although there was some variation between the results of different technics on the same sample of blood, in general, the results were consistent.

It is the opinion of the authors that, from the evidence presented, a diagnosis of asymptomatic syphilis based upon positive serology alone should not be made in an area where malaria is endemic without first eliminating the possibility of coincident malarial infection.

Complement-Fixation in Rickettsial Diseases*

IDA A. BENGTON, PH.D., AND NORMAN H. TOPPING, M.D.

*Senior Bacteriologist, and Passed Assistant Surgeon, U. S. Public Health Service,
Washington, D. C.†*

THE complement-fixation reaction has been found useful in the study of a number of bacterial diseases and, more recently, in certain virus diseases including influenza, psittacosis, equine encephalomyelitis, lymphocytic choriomeningitis, lymphogranuloma venereum, papilloma, vaccinia, and others.

Complement-fixation in rickettsial diseases has been investigated by comparatively few workers. Among the early publications was that of Davis and Petersen,¹ 1911, who studied complement-fixation in Rocky Mountain spotted fever, using as antigens the serum and the macerated organs of infected guinea pigs and also infected tick eggs. Alcoholic extracts of organs from fatal cases of European typhus were used as antigens by several workers including Cathoire,² Müller,³ Markl,⁴ Delba,⁵ and Papamarku.⁶ Papamarku⁷ later used an extract of infected lice as did Jacobthal^{8,9} and Epstein.¹⁰ None of these antigens yielded results which were very satisfactory. In all probability the number of rickettsiae in the infected organs was too small for the purpose of producing good antigen. Infected lice were unsuitable because

similar results were obtained with both normal and with infected lice.

With the newer improved methods for the cultivation of rickettsiae it has been possible to obtain much more satisfactory antigens. This is particularly true of endemic typhus and "Q" fevers. Endemic typhus fever rickettsiae grow abundantly in the infected chick yolk sac (Cox¹¹) in the lungs of mice and rats infected by the intranasal route (Castaneda¹²), and also by the agar-tissue culture method of Zinsser, Fitzpatrick, and Wei.¹³ The rickettsiae of "Q" fever can be obtained in considerable concentration in the spleens of infected mice (Burnet and Freeman¹⁴), and in the infected yolk sac of chick embryos. It is a more difficult problem to obtain luxuriant growth of the rickettsiae of Rocky Mountain spotted fever and European typhus.

Castaneda,¹⁵ 1936, obtained positive complement-fixation reactions in cases of active and past infection with Mexican typhus and Brill's disease, using rickettsiae from x-rayed typhus infected rats as antigen.

One of us has recently reported on complement-fixation in "Q" fever¹⁶ and in endemic typhus.¹⁷ Mouse spleens and infected yolk sacs were the source of the rickettsiae used for antigens in "Q" fever and infected rats' lungs and infected yolk sac were employed for the typhus antigens.

* Read before the Laboratory Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 16, 1941.

† From the Division of Infectious Diseases, National Institute of Health, U. S. Public Health Service, Bethesda, Md.

In the complement-fixation reaction as well as in other laboratory procedures used for determining active or past infection an important consideration is that of specificity, and the work here reported has been undertaken to obtain added information on this point, particularly in regard to endemic typhus fever and its differentiation from Rocky Mountain spotted fever. The Weil-Felix test has proved very useful in the differentiation of certain of the rickettsial diseases from other diseases, but it does not differentiate between typhus and spotted fever. The neutralization test in guinea pigs also fails at times to yield conclusive results, owing to secondary infections and nonspecific immunity (Badger¹⁸). The question of differentiation is of special importance in those sections of the country where both endemic typhus and Rocky Mountain spotted fever occur, as in the eastern and southeastern sections of the country (Dyer¹⁹).

Materials—The sera used in carrying on this study include: (1) sera from cases of past infection with either endemic typhus or Rocky Mountain spotted fever; (2) sera from active cases of endemic typhus or Rocky Mountain spotted fever; (3) sera from patients with other diseases.

The typhus antigens were prepared by grinding the yolk sacs of infected chick embryos in the 5th or 6th passage when they showed numerous rickettsiae, with sterile alundum, after draining to remove some of the yolk. A 10 per cent suspension in 0.85 per cent sterile saline with 1:10,000 merthiolate was prepared. This was centrifuged at low speed in the horizontal centrifuge in order to remove the larger particles. The supernatant fluid was then centrifuged for 1 hour at 4,000 r.p.m. The precipitate was suspended in 0.85 per cent saline containing merthiolate to the original volume. The precipitate which settled from this sus-

pension after standing 1 to 2 days was discarded. Further tissue precipitate settles on standing, but it has been found that this is not anticomplementary and the suspension may be shaken at the time of titration or for later use. The antigens were titrated to determine the lowest concentration at which fixation was obtained with a pooled specimen of known sera.

Methods—All of the specimens, both from the typhus and spotted fever cases, were tested against the endemic typhus antigen. Only a few tests were made with spotted fever antigens. The test was carried out as has previously been described, using 0.2 ml. amounts of inactivated sera in dilutions ranging from 1:2 to 1:256 or higher, 0.2 ml. amounts of antigen, and 0.2 ml. amounts of complement. After 1 hour's incubation, 0.4 ml. of sensitized sheep cells was added and incubation continued for another hour. After storage in the refrigerator over night readings were made the following morning. Fixation at 3+ or 4+ was considered a positive test.

RESULTS

1. *Non-rickettsial diseases*—It might be expected that the complement-fixation test would be specific as far as non-rickettsial diseases are concerned. This was found to be true among those investigated. Included were 14 cases of tuberculosis, 10 cases of leprosy, 6 cases of malaria, 10 cases of syphilis, 10 cases of rheumatic fever, 13 cases of tularemia, 7 cases of undulant fever, 8 cases of typhoid fever, 8 cases of trachoma, 2 cases of lymphopathia venereum, 1 case of psittacosis, and 2 cases of amebiasis (Table 1). These sera were freshly drawn, with the exception of some of those from undulant fever, tularemia, and typhoid, which had been stored for periods of several weeks at icebox temperature. Slight fixation occurred in the lower dilutions in certain of the leprosy, undulant fever, and tula-

TABLE 1
Complement-fixation in Non-rickettsial Diseases

<i>No. of specimens</i>	<i>Disease</i>	<i>Complement-fixation</i>	<i>Remarks</i>
14	Tuberculosis	0	
10	Leprosy	0 to very slight	7 fixed complement in dilution 1:2 (1+ or 2+)
6	Malaria	0	2 cases active 2 cases cured
10	Syphilis	0	2 cases with tabes dorsalis 3 cases primary 3 cases secondary 4 cases tertiary
10	Rheumatic fever	0	
7	Undulant fever	0 to very slight	6 fixed complement in dilutions 1:2 to 1:4 (1+ or 2+). Titers against abortus antigen were 1:160 to 1:5120.
13	Tularemia	0 to very slight	7 fixed complement in dilutions 1:2 to 1:8 (1+ or 2+). Titers against tularense antigen were 1:8 to 1:1280.
8	Typhoid fever	0	
8	Trachoma	0	2 cases papillary 1 case granular 1 case cicatricial
2	Lymphopathia venereum	0	
1	Psittacosis	0	
2	Amebiasis	0	

remia cases, but these were usually incomplete and not higher than 1:2 or 1:4 dilutions. All of the undulant fever cases were positive by agglutination in dilutions 1:160 to 1:5,120 against *Brucella* antigen, and the tularemia cases were positive against tularense antigen in dilutions 1:8 to 1:1,280.

2. *Active and past endemic typhus infections*—The study of known typhus cases has been extended beyond that previously reported. The complement-fixation titers and the Weil-Felix titers of a series of specimens from a case of endemic typhus resulting from a laboratory infection have been determined (Figure 1). The complement-fixation titer increased from 1:8 on the 10th day to 1:4,096 on the 15th day, then fell to 1:2,048 on the 16th day. On the 85th day the titer was 1:1,024 and on the 180th day 1:512, thus showing a gradual decrease. The Weil-Felix titer ran approximately ten times as high as

the complement-fixation titer on the 15th or 16th day and fell off more rapidly, reaching 1:320 on the 85th day and 1:160 on the 180th day. A positive test by the Weil-Felix reaction was evident earlier than by complement-fixation, a titer of 1:80 being reached on the 6th day, 1:320 on the 9th day, and 1:1,280 on the 10th day.

In another case of typhus, originating as the result of a laboratory infection, the development of complement-fixing antibodies was much slower (Figure 2), a titer of 1:2 being reached on the 6th day, 1:4 on the 7th day, and 1:8 on the 14th day. The corresponding Weil-Felix titers were 1:320 to 1:5,120. This appears to have been an exceptional case. By 3 months the complement-fixation titer was 1:512 and the Weil-Felix titer 1:640.

Sera from 53 cases of past infection with endemic typhus were tested by the complement-fixation and Weil-Felix

COMPLEMENT FIXATION AND WEIL-FELIX TITERS
OF SERUMS FROM A CASE OF ENDEMIC TYPHUS

FIGURE 1

methods. All of these cases had occurred in Georgia and Alabama. The dates of occurrence varied from 2 months to 67 months prior to the time the sera were drawn. Fifteen cases were proved cases of endemic typhus, the virus having been isolated in guinea pigs. The diagnoses of the remaining 38 cases were based on clinical symptoms. It is possible that some of the cases which showed low titers may have been incorrectly diagnosed. It is significant, however, that the results of the tests agree so well with the diagnoses of the physicians, though it is to be considered that these cases occurred in a section of the country where the disease is endemic and therefore perhaps more likely to be correctly diagnosed.

The results obtained with these 53 cases are shown in Figure 3. The number of months elapsing between the date of onset and the date when the serum was obtained are represented by the abscissae and the complement-fixation and Weil-Felix titers by the ordinates. The graphs represent the average titers of all of the sera which were drawn at approximately the same length of time after onset of illness. It is very probable that the severity of the

infection, as well as the length of time elapsing since onset, influences the titer of the serum, hence the irregularities in the titers. The general trend of the graph representing the complement-fixation titers indicates a rather gradual decrease in this titer. If we assume that, at certain stages at least, the Weil-Felix titer is approximately ten times that of the complement-fixation titer, it is obvious that in general the Weil-Felix titers in these samples are much lower than the corresponding complement-fixation titers, though it is to be noted that all of these cases had occurred 2 months or more prior to the time the serum was obtained. Only one serum

COMPLEMENT FIXATION AND WEIL-FELIX TITERS OF SERUMS
FROM 53 CASES OF PAST INFECTION WITH ENDEMIC TYPHUS.

FIGURE 3

had a Weil-Felix titer higher than 1:320 in 6 months, and after this none was higher than 1:160, and the majority had titers of 1:80, 1:40, or lower. The complement-fixation titers with a few exceptions were 1:16 or higher even in one case which had occurred 5½ years previously. It is, therefore, evident that the complement-fixation titer of the serum is a much better criterion of past infection than is the Weil-Felix titer.

3. *Endemic typhus and Rocky Mountain spotted fevers*—The specificity of the complement-fixation test for endemic typhus has been further investigated by a comparative study of the results obtained with serum from active cases of endemic typhus and Rocky Mountain spotted fevers against a typhus antigen. A few cases of past infection are also included in this group. In the typhus group are 11 active 1941 cases and 4 cases of past infection. The Rocky Mountain spotted fever cases include 20 active 1941 cases and 10 cases of past infection, 2 of which occurred in 1939 and 8 in 1940. The sera from most of the active cases are those received at the National Institute of Health with requests for the Weil-Felix test, or for the complement-fixation test, or for tests to differentiate between

endemic typhus and Rocky Mountain spotted fever. A number of sera from cases of both endemic typhus and Rocky Mountain spotted fevers have been received from the branch Typhus Research Laboratory of the National Institute of Health at Savannah, Ga., and others from the Georgia State Health Department.

In order to evaluate the results of the tests, an effort has been made to obtain all the information necessary from the clinical standpoint for a diagnosis, using records from the hospitals or attending physicians. This information includes age and sex of patient, locality where the case occurred, date of onset of illness, history of tick or flea exposure, clinical symptoms, date of appearance, location and description of rash, the date when the specimen was obtained, and the physician's diagnosis.

Weil-Felix tests and complement-fixation tests were done on all specimens, using an endemic typhus antigen as previously stated in all the complement-fixation tests whether the sera were from cases diagnosed as endemic typhus or Rocky Mountain spotted fever. It was anticipated that positive results would be obtained in all the typhus cases and that probably negative

* Immunity tests by Dr. George D. Brigham, Typhus Research Laboratory, Savannah, Ga.

results would be obtained in the spotted fever cases.

Considering the endemic typhus cases (Table 2), it was found that all of these gave positive results in comparatively high dilutions, none being lower than 1:128 and several as high as 1:4,096 and 1:8,192. Among the active cases, the shortest time recorded between the date of onset and the date of obtaining the serum was 9 days, and in this case the complement-fixation titer was 1:256. One of the highest titers recorded, 1:8,192, was on the 16th day. All of the results obtained in these tests were definite and clear-cut, and usually the titer dropped sharply from positive to negative. In those cases having a high complement-fixation titer the Weil-Felix titers were usually correspondingly high. Also in the 3 cases of past infection the results with the complement-fixation test were definite, the titers ranging from 1:256 to 1:1,024.

The majority of these cases were adults living in the eastern or south-eastern sections of the country and several gave a history of contact with

rats. The rash in most cases was typical of endemic typhus, occurring first on the body.

The 30 cases of Rocky Mountain spotted fever (Table 3) in contrast to the endemic typhus fever gave negative results for the most part in tests against endemic typhus antigen, though positive Weil-Felix agglutination titers were obtained in fairly high dilutions in a number of cases. All of the 10 cases of past infection which occurred from 8 months to 2 years prior to the test gave negative results in the complement-fixation test.

The active cases of Rocky Mountain spotted fever date from April 23, 1941. Eighteen specimens from 14 cases were all completely negative against endemic typhus antigen (Table 4).

The sera from 8 cases showed some cross-fixation with typhus antigen (Table 5). In probably none of the above cases was fixation present in a high enough titer to be considered significant, with the exception of the one case, K.T., in which complete fixation was obtained in the dilution of 1:256

and partial in the 1:512 dilution. This case was a 3 year old child from whom ticks had been removed and who had had a rash typical of Rocky Mountain spotted fever. This specimen was taken on the 14th day, at which time the Weil-Felix titer was 1:20,480. A second specimen taken on the 54th day of illness was completely negative for typhus by the complement-fixation test, while it had a positive Weil-Felix in the 1:1,280 dilution. The high Weil-Felix titer may bear some relationship to the high cross-fixation titer or the possibility may be considered that this case may have suffered a previous typhus infection, since the locality was one in which endemic typhus prevails.

In repeated tests on the above specimens in which some cross-fixation occurred, it was found that fixation could be reduced by using a more dilute antigen, titration of the antigen being made against known typhus sera in order to insure that dilution was not carried past the point where positive results would be obtained. It was thus found possible to dilute some of the antigens as much as 1:32.

COMMENT

The question of the best method for the early diagnosis and the differentiation between typhus and Rocky Mountain

spotted fever is one which cannot be answered completely at the present time. The Weil-Felix test has proved very useful as a diagnostic test for certain rickettsial diseases without differentiating between them. The complement-fixation test for endemic typhus is positive in sufficiently high dilutions in general to exclude Rocky Mountain spotted fever. In some cases positive results were obtained in dilutions of 1:256 on the 9th or 10th day after onset. There may occasionally be some confusion between early cases of typhus or those of typhus in which complement-fixing antibodies develop slowly (see Figure 2), and cases of Rocky Mountain spotted fever which are more advanced or in which there is a rapid development of antibodies. However, this subject can be more adequately studied when studies similar to these reported are made with spotted fever antigens.

SUMMARY

The complement-fixation test for endemic typhus is of value in the detection of active or past infection. Titers of 1:128 and 1:256 may be reached on the 9th or 10th day of illness and 1:4,096 and 1:8,192 on the 14th or 15th day.

The complement-fixation reaction is a better criterion of past infection with endemic typhus than is the Weil-Felix

test as complement-fixing antibodies may be present in significant dilutions up to 5 or more years after the illness.

The complement-fixation test may probably be used to differentiate between endemic typhus and Rocky Mountain spotted fevers. Spotted fever sera tested against a typhus antigen as a rule give a negative reaction, while at the same time a positive Weil-Felix reaction may be obtained in quite high dilutions of serum. Occasionally there may be some cross-fixation of typhus antigen by spotted fever sera, but usually in low dilutions. Tests similar to those reported in which a spotted fever antigen is used may elucidate this phase of the problem.

Developing a Comprehensive Health Service in Puerto Rico*

E. GARRIDO MORALES, M.D., DR.P.H., F.A.P.H.A.

Commissioner of Health, San Juan, Puerto Rico

GEOGRAPHICALLY Puerto Rico lies midway between the North and South American continents—a sentinel in the path of possible approaches of attack against the Western Hemisphere, but also a way station in the routes of peaceful communication, and a stepping stone to friendly relations between the Americas. Puerto Rico is, therefore, well fitted to become the meeting place of the peoples of this hemisphere for the furthering of common interests and the development of useful and highminded initiatives, especially in the field of public health administration and research.

Toward this end no enterprise could be more useful, no initiative more altruistic than the organization of technical and scientific work for the promotion and preservation of the public health. It is, therefore, with deep satisfaction and high hope that we have founded the Puerto Rico Public Health Association, whose self-imposed task is "to promote the public health by bringing together in closer association persons professionally engaged or interested in public health, by furthering their scientific advancement, by helping to spread public health knowledge, by stimulating and promoting research in public health and hygiene, by aiding in the adoption of legislation in the interest of public

health, and by volunteering assistance in times of stress or need."

The new association will not only thus come as a very welcome aid to the labors of the Health Department, but will also contribute to a better understanding between our fellow workers from the two continents. The association will also help materially to increase our efficiency in the field of public health, with benefit not only for our own Insular people but also for the nation as a whole and the continent at large.

Effective, conscientious training is absolutely essential for the success of any public health program that aspires to be of more than momentary significance. This is the reason why the Insular Department has always striven to engage the services of well trained men and women. To achieve this end, several years ago the Health Department organized a training center for nurses, sanitarians, and laboratory technicians, where short courses lasting from 6 to 8 weeks were given. In addition, through the facilities generously extended to it by the Rockefeller Foundation, the department was able to select a number of physicians, public health nurses, and sanitary engineers to hold fellowships for the purpose of pursuing graduate studies in the United States. These persons, upon their return to Puerto Rico, were placed in key positions within the department.

* Address at the inaugural meeting of the Puerto Rico Public Health Association, San Juan, P. I., September 23, 1941.

As a natural result of these efforts, a Department of Public Health was created a year ago at the School of Tropical Medicine, San Juan, in coöperation with the University of Puerto Rico, Columbia University, and the Insular Department of Health, for the graduate training of physicians, sanitarians, technicians, and nurses. The curriculum embraces an extensive program, lasting a year, and includes the usual special courses to meet the needs of the students. The Public Health Unit at Rio Piedras has been reorganized to function as a modern experimental unit and as a specialized center for public health practice in the field. At the beginning of this scholastic year the facilities for the training of our personnel have also been extended by inaugurating a one year course of study for social workers in the College of Education of the University of Puerto Rico.

In Puerto Rico a low standard of living, with illness and widespread suffering, results from the geographical limitations, with extremely high population density, limited natural resources, lack of major industries, a large amount of unemployment and low wages. Such conditions are aggravated by the presence of a number of endemic diseases, notably malaria and hookworm, which are widely prevalent in tropical and subtropical districts. However, a large part of the illness on the Island is susceptible to control measures if funds become available.

The present Commissioner of Health was appointed during the year 1933, and a program was formulated which contemplated an attack on the fundamental problems responsible for a high mortality and considerable disease prevalence. Among other things this program provided for the extension of public health units under full-time medical officers to cover the 76 municipalities, organization of services for tuberculous patients based on sound

epidemiological principles, an island-wide program for treatment of venereally infected persons, extensive measures in rural sanitation and malaria control, and adequate hospital facilities for the care of the underprivileged population on the Island.

The first public health unit had been organized in the town of Rio Piedras during the year 1926; in 1933 there were 32 municipalities with this type of service, and during 1938 the entire territory of the Island, consisting of 76 municipalities, was being served by local public health units. In continental United States, where these units began to be organized more than 25 years ago, there were recently only 15 states with the entire territory covered by full-time health service, and in South American countries, although these agencies are rapidly being organized, their establishment is only in an early stage.

As a part of the tuberculosis program, hospital beds for the isolation of indigent patients were increased by 1,000, and treatment centers for ambulatory patients are being operated in 20 districts. An average of 75,000 fluoroscopies and 40,000 x-ray examinations are performed annually by trained physicians in these centers as a part of the case finding program. Approximately 3,000 tuberculous patients are hospitalized and over 5,000 are given artificial pneumothorax every year, with the result that in approximately 50 per cent of such cases the sputum is converted from positive to negative, eliminating a large number of foci of infection from the community. As a consequence of this program the mortality from this disease has dropped from a rate of 337 per 100,000 population in 1933 to a rate of 258 during the year 1939, a decrease of 23 per cent.

According to studies made by the Insular Health Department, 10 per cent of the urban and 5 per cent of the rural population have a positive serology for

syphilis. With the extension to Puerto Rico of the benefits of the La Follette-Bulwinkle Act, together with an appropriation of the Insular Legislature, it has been possible to operate 35 dispensaries throughout the Island for the diagnosis and treatment of venereal disease patients. Approximately one-half million complement-fixation and flocculation tests for the diagnosis of syphilis were performed last year, and not less than 20,000 indigent persons received treatment for which they could not afford to pay.

The large majority of the inhabitants in the rural districts earn wages which are entirely inadequate to provide their families with food, shelter, and other elementary needs of civilized people. Because of this fact, approximately 50 per cent of the homes in rural communities have no sanitary facilities, the soil contamination contributing to the spread of hookworm and other filth-borne diseases. In coöperation with the Works Progress Administration, the Insular Health Department is carrying out a project to provide rural homes of indigent persons with sanitary privies. During a period of approximately two years, 24,000 such privies have been constructed in 18 factories and distributed to indigent persons.

With 90 per cent of the families of this Island receiving an income of less than \$500 per year per family, medical care to the underprivileged has to be a responsibility of the government. Up to 1938 such care was provided in municipal hospitals which lacked the necessary equipment and trained personnel required by modern medical standards. Because of this fact, a program has been formulated for the centralization of such services in the Insular Government and provision has been made for seven large district hospitals with a capacity of 300 beds each, including services of surgery, medicine, obstetrics, and pediatrics. Four of these

hospitals have already been constructed, three of which have been adequately equipped and are in full operation. Equipment for the fourth hospital is being purchased at the present time and it will begin to function in the near future.

With the extension to the Island of the benefits of Titles V and VI of the Social Security Act, funds became available for the expansion of the public health program. Additional prenatal and infant hygiene clinics were opened in several municipalities, providing added facilities greatly needed for the care of infants and expectant mothers; part-time dentists were added to the staff of local health units in ten municipalities; two mobile dental units were purchased which are being used in rural districts; orthopedic care is being provided to the crippled; a nutrition program is being developed and additional public health nurses, social workers, laboratory technicians, and sanitarians have been employed to expand the scope of the local health unit program.

In connection with national defense numerous activities are being developed by the Insular Health Department to protect the armed forces stationed on the Island. A large part of the physical examinations carried out among the draftees were performed by members of the Health Department staff; blood tests have been made among 20,248 selectees, and those that showed a positive serology are receiving adequate treatment in the clinics in order to restore them to the service in the army; a total of 9,805 x-ray films of the chest have been taken among men who passed the physical examination for army duty in the local boards of the Selective Service, in order to eliminate the physically unfit, and malaria control work is being carried out intensively in the neighborhood of army camps to protect the health of the armed forces.

Because of its geographical location,

its vast culture acquired during past centuries, the bilingual advantages of its people as well as its political and scientific connections with the United States, Puerto Rico is especially well suited to act as an aid to continental solidarity and to serve as a meeting ground for inter-American conferences. To this end the first Inter-American Institute for Hospital Administrators was held in San Juan during the period December 1-13, 1940, under the auspices of the American College of Hospital Administrators and the American Hospital Association, and in coöperation with the University of Puerto Rico, the Insular Department of Health, the Puerto Rico Medical Association, the School of Tropical Medicine, the Territorial Charities Board, and the Puerto Rico Hospital Council. Distinguished visitors from the continent as well as

representatives from seven South and Central American republics participated in the conference.

I am confident that the foundation of a public health association in Puerto Rico will be a useful step in achieving high professional levels. It also will contribute to a higher standard of work and to make the particular health problems of the Island better known and better understood in the continental United States.

Healthy citizens are the foundation of a strong nation. In the present national emergency the Puerto Rico Department of Health will use every means available to improve the stamina of the people, adding its efforts to the national program and coöperating in the task of making the nation a stronger and healthier champion of democratic institutions.

Field Study of the Prophylactic Value of Pertussis Vaccine*

JAMES E. PERKINS, M.D., DR.P.H., ERNEST L. STEBBINS, M.D., M.P.H.,† HILDA FREEMAN SILVERMAN, PAUL A. LEMBCKE, M.D., M.P.H.,† AND BERNARD M. BLUM, M.D., M.P.H.†

Division of Communicable Diseases, New York State Department of Health, Albany, N. Y.

A CONTROLLED study of the prophylactic value of Phase I pertussis vaccine was conducted in Binghamton, N. Y., from January 1, 1939, to November 1, 1940. The vaccine was prepared in the same manner as that used by Pearl Kendrick and Grace Eldering in their Grand Rapids, Mich., study¹ and was furnished by the Michigan State Health Department Laboratories. Three subcutaneous injections of 2.0 ml., 3.0 ml., and 3.0 ml., respectively, or a total of 8.0 ml. (80 billion organisms) were given at weekly intervals to children eligible for the study. Children from 6 months through 4 years of age attending the Binghamton City's well baby clinics were considered eligible if they had no history of pertussis or pertussis immunization.

In connection with another investigation conducted at the same time, each eligible child was given a hemolytic streptococcus toxin skin test, and every other child was given the pertussis vac-

cine as well. The children receiving only the skin test were kept as controls. The vaccinated children were entered in the study on the date of the last injection, while each control child was entered 2 weeks from the date of the skin test, so as to be entered at the same time as the corresponding vaccinated child. When there was more than one eligible child in a family, the practice of vaccinating the younger child was alternated with that of vaccinating the older child, to equalize the age distribution in the control and vaccinated groups. Only occasionally was it found impossible to follow this schedule, since the mothers were in the habit of accepting without question the recommendations of the woman pediatrician in charge, who had served in this capacity for many years.

Reactions to the vaccine were negligible.*

Five hundred and ninety-three children were given the complete series of injections. Excluding 6 who moved out of town immediately after the last

* Read before the Epidemiology Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

† Dr. Stebbins is now Professor of Epidemiology, DeLamar Institute of Public Health, Columbia University; Dr. Lembcke is District Health Officer, New York State Department of Health, Rochester; and Dr. Blum is District Health Officer, New York City Department of Health.

* The sole reaction which might be classified as severe occurred in a 22 months old boy who developed convulsions and fever following the first injection. No further inoculations were given. This child's history indicated a proneness toward convulsions following relatively slight stimuli.

inoculation, 587 children formed the vaccinated group. The control group consisted of 699 children.

Table 1 shows the number of vaccinated and control children under observation during each month. It will be noted that in spite of plans there was a slight lag in the entering of controls compared with vaccinated children during the first 6 months, so that when all of the immunizations had been completed (August, 1939), the vaccinated group was furnishing a somewhat greater number of person months of observation than the control group. It was decided, therefore, to admit to the study as control children all infants in study families as they reached 6 months of age. As a result, it will be observed that although the person months of observation in the vaccinated group progressively declined from September, 1939, the person months of observation of the control group levelled off, and toward the last slightly increased. The table indicates, however, that the person months of observation for each group were approximately the same for each month throughout the entire period. Taking the study as a whole, there was a total of 9,563 person months of observation for the vaccinated group, and 9,122 for the control group; or in terms of person years,

797 for the vaccinated group, and 760 for the control group.

METHOD OF OBSERVING STUDY CHILDREN

Every study family was visited once a month by a nurse to determine the occurrence of any illness during the interval in any member of the household. Two, and later, three nurses devoted their entire time to this visiting of families. All the nurses were on the regular staff of the Division of Public Health Nursing of the State Department of Health, and had the status of either supervising nurse or communicable disease consultant. In addition to the routine monthly visits, a call was made immediately upon a report from the family that an illness had occurred in the home, or upon the receipt of a report by the City Health Department indicating that whooping cough had been diagnosed in a member of the study household.

Every illness considered at all suspicious of whooping cough was referred by the nurse to a physician for investigation. The physician for this purpose was one of the two regularly employed epidemiologists in the Division of Communicable Diseases in the State Health Department. Unavoidable changes in personnel during the study period, how-

ever, resulted in four different epidemiologists serving in this capacity. In investigating a suspected case of pertussis, the epidemiologist recorded the presence or absence of the characteristic whoop; presence and severity of paroxysms, vomiting, cyanosis and weight loss; laboratory findings; final opinion as to whether it was a definite case, suspicious case, or apparently not a case; and if considered to be a case, whether it was considered mild, moderately severe, or severe. The source cases

in all alleged exposures were similarly investigated by the epidemiologist. White blood counts and cough plates* were used in diagnosis of cases, but both were found to be of relatively little assistance.

The epidemiologists were unaware as to which children had been vaccinated and which ones were controls, and ac-

* Of 28 cough plates from vaccinated children with suspected pertussis, none was positive. Of 65 plates from control children with suspected pertussis, 15 were positive.

cidentally learned of the status of a child in only the occasional instance.

COMPARABILITY OF THE VACCINATED AND CONTROL GROUPS

A study of the classification of the vaccinated and control children according to economic status of the family, as estimated by the nurse, reveals that the vaccinated group had a somewhat greater percentage of children from homes of good economic status (Table 2). This slight disproportion is similarly indicated in an analysis of the two groups by the number of individuals per household (Table 3). A somewhat larger percentage of the children in the vaccinated group came from households of only three members and, conversely, a somewhat larger percentage of control children came from households with eight or more individuals.

In all other respects, the two groups seem to be entirely comparable, so far as one may judge by the various criteria available for comparison. From Table 4 it is obvious that the two groups were evenly distributed geographically throughout the City of Binghamton, and Table 5 indicates that the two groups are comparable from the standpoints of age, sex, previous history of tonsillectomy, measles, and of scarlet

* Vomiting had to occur more than once to be counted at all.

† So classified only if there is a history of exposure to a definite or suspicious pertussis case within 35 days of onset in this source case and the onset of cough in the exposed child occurred not earlier than 5 days from first exposure, nor later than 21 days subsequent to the last exposure.

in the decision as to whether or not a given illness was whooping cough, the evaluation was based upon the individual symptoms and findings indicated on the case history sheet, rather than merely upon the opinion expressed by the epidemiologist. Arbitrary criteria were established for determining whether or not a given case was to be considered whooping cough. These criteria are presented in Table 6. It will be noted that a definite diagnosis of pertussis was made if the child's cough lasted for 14 days or more and there was a history of a characteristic whoop or if a positive cough plate was secured. In no instance was a history of a characteristic whoop or a positive cough plate secured from a child with a cough of less than 14 days' duration. In addition, a case was considered definitely whooping cough if the child had a cough with a duration of 14 days or more, and suf-

The annual pertussis attack rates per 100 children based on these arbitrary criteria, are found in Table 7. Among the control children there occurred 101 definite and 24 suspicious cases of whooping cough, while among the vaccinated group there were only 42 definite and 19 suspicious cases. On the basis of definite cases alone, this results in an annual attack rate of 13.3 cases per 100 children among the control group, and a rate of 5.3 for the vaccinated group. The ratio of the rate among the control group to that among the vaccinated group is 2.5. When the suspicious cases are added, the rates become 16.4 among the vaccinated, and 7.7 among the controls, or a ratio in the rates of 2.1 to 1.

It will be recalled that there was some disproportion so far as economic status was concerned between the vaccinated and control groups. Although

TABLE 7

Controls	760	101	24	125	13.3	16.4
Ratio control rate to vaccinated rate					2.5	2.1

fered both paroxysms and vomiting. Incidentally, vomiting following a coughing spell had to occur more than once to be counted at all.

A cough was classified "suspicious whooping cough" if its duration was 14 days or more and the child suffered either paroxysms or vomiting, but not both, or if a child had a cough of less than 14 days' duration and had both paroxysms and vomiting. Any cough less definite than this, but occurring after exposure to a definite or suspicious pertussis case, was noted and designated "possibly subclinical pertussis."

the attack rates were somewhat lower among those of good economic status (Table 8), and although there was a larger proportion of these children in the vaccinated group, this disparity is insufficient to account for the lower rate among the vaccinated children. The ratios of 2.5 and 2.1 remain unchanged when the attack rates among the control and vaccinated groups are adjusted for economic status.

RELATIVE SEVERITY OF PERTUSSIS ATTACKS

As to the relative severity of the

definite cases of pertussis which occurred in the control and vaccinated groups, arbitrary criteria were established for classification, again based upon the epidemiologist's indication of the severity of the individual symptoms, rather than upon his final opinion as to the severity of the case as a whole. The criteria adopted are presented in Table 9. Paroxysms and vomiting were each

 moderate, " 2
 severe, " 3
If weight loss is indicated, count 2
Calculation:
If the sum of above is: 3 or less, classify attack as mild,
 4 or 5, " " as moderate
 6 or more, " " " severe

Comment:
If pneumonia developed within 21 days of onset the attack is classified as severe regardless of other criteria.
Vomiting had to occur more than once to be counted at all.

given numerical values of 1 for mild, 2 for moderately severe, and 3 for severe. Loss of weight was given a value of 2. Upon adding the numbers in a given case, the attack was classified as mild if the sum was 3 or less; moderate, if the sum was 4 or 5; and severe, if the sum totaled 6 points or more. An exception was made if pneumonia de-

veloped within 21 days of onset; the attack was classified as severe under these circumstances regardless of other criteria. The necessity for applying this last rule occurred in only one instance.
The result of classifying the cases in accordance with these standards is presented in Table 10. It will be noted that 79 per cent of the cases among the vaccinated group were classified as suspicious or mild, in comparison with 54 per cent among the control group. Sixteen per cent of the cases in the vaccinated group were considered moderately severe, compared with 30 per cent among the controls. Only 3 cases in the vaccinated group were classified as severe, or 5 per cent, compared with 20 cases, or 16 per cent, among the cases in the control children.
The same data presented as annual attack rates per 100 children are indicated in Table 11. It will be noted that for each classification, the rate is higher in the control group than in the

TABLE 11
Prophylactic Pertussis Vaccine Study
Binghamton, N. Y.

* That is, coughs following exposure to pertussis but so mild could not be classified as "suspicious." These rates are based upon 39 cases among the vaccinated group, and 27 cases among the control group.

vaccinated group, with a ratio of the control to vaccinated rates progressively increasing from the suspicious cases, with a ratio of 1.3, to the severe cases with a ratio of 6.5. To this table has been added the rates for "possibly subclinical pertussis." These coughs, as mentioned above, are those which did not meet the criteria for suspicious cases of pertussis, but which occurred within the incubation period of whooping cough following exposure to a definite or suspicious case. Coughs due to infection with *Hemophilus pertussis* which cannot be recognized by the ordinary diagnostic criteria undoubtedly occur, but would be expected more

frequently in the vaccinated group if the vaccine were of value, since some cases which ordinarily would be sufficiently severe to permit recognition might be thus modified into subclinical attacks. It will be noted in Table 11 that the attack rate for these cases of "possibly subclinical pertussis" is higher among the vaccinated group than in the control group, contrary to the other classifications in the table, and results in a ratio of 0.7. It will be recalled from Table 5 that coughs similar to these, except for the lack of a prior history of pertussis exposure, occurred with equal frequency in the two groups.

INCIDENCE FOLLOWING EXPOSURE

Analysis of the data may also be made upon the basis of history of exposure to pertussis and the percentage of cases of pertussis developing therefrom. Data on this basis are given in Table 12. It will be noted the exposures are separated into household exposure and extra-household exposure. For purposes of this analysis, a history of exposure was counted as such only if it was to a confirmed definite case within 21 days of onset in this source case, and with onset in the exposed child occurring not earlier than 5 days from first exposure nor later than 21 days subsequent to the last exposure. Only

TABLE 12
Prophylactic Pertussis Vaccine Study
Binghamton, N. Y.

Exposures to Pertussis During Observation Period and Cases Apparently Resulting Therefrom

	In Own Household		Outside Own Household	
	Vaccinated	Controls	Vaccinated	Controls

Per cent exposures resulting in cases	38.6	84.8	11.2	39.8
Ratio control rate to vaccinated rate	2.2		3.6	

* Only one exposure counted per child. If multiple exposures, the most intimate one occurring 5 to 21 days prior to onset was counted.

Child considered exposed only if diagnosis in source case was confirmed as definitely pertussis, and exposure took place during first 21 days of illness in source case.

one exposure was counted per child. If a child suffered more than one exposure, the one tabulated was determined from a priority list of possible combinations of exposures, which gave preference to the more intimate exposure, and one resulting in illness and the more definite attack.

Considering first only the household exposures, it will be noted that 44 such exposures were observed among the vaccinated group and 46 among the control children. The exposures in the vaccinated group resulted in 14 definite cases, or 32 per cent. In contrast, household exposures among the control group resulted in 33 cases, or 72 per cent. If suspicious cases are included, the percentages become 39 and 85, respectively, for the vaccinated and control groups. The 85 per cent in the control group agrees well with numerous other studies showing the percentage of susceptible children developing pertussis upon household exposure. Considering extra-household exposure, again the numbers of histories of such exposure are very similar in the two groups; 98 among the vaccinated group and 103 among the controls. These exposures in the vaccinated group resulted in only 8 cases, or 8 per cent, while those in the control group resulted in 36 cases, or 35 per cent. Adding the suspicious

cases, the percentages become 11 and 40, respectively. It will be noted that the ratio of the per cent in the control group to that in the vaccinated group is distinctly higher with regard to extra-household exposure than with reference to household exposure (4.3 and 2.3, respectively, for definite cases, or 3.6 and 2.2, respectively, for definite and suspicious cases combined). If the vaccine is of value this might be expected, since it might produce sufficient immunity to protect against a transitory extra-household exposure but not enough to protect against the more intense household exposure.

HOUSEHOLD SECONDARY ATTACK RATES

A third method of analysis is on the basis of household secondary attack rates (Table 13). The numbers are very small in this study, but consistently in each age group there is a higher secondary attack rate among the control group, compared with the vaccinated group. Taking all ages, these rates are 34 per cent among vaccinated children, compared with 79 per cent among controls.

COMPARISON WITH OTHER STUDIES

This study was conceived and instituted when the Grand Rapids¹ and Cleveland² studies were the most impor-

two investigations. A comparison of the results in this study with those in the Grand Rapids and Cleveland studies, is presented, therefore, in Tables 14 and 15.

It should be kept in mind that there are certain differences in the manner in which these three studies were conducted. The more important of these relate to the preparation of the vaccine, dosage, and children used in the study. The Grand Rapids and Binghamton vaccines were supposedly identical and both prepared in the Michigan State Health Department Laboratories. The Cleveland vaccine was also a Phase I vaccine containing 10 billion organisms per ml., but in its preparation the organisms had been washed once with distilled water, while the Michigan vac-

total dose of 7 ml. instead of the 8 ml. in the other two studies. In the Cleveland study only children between the ages of 6 and 15 months were used, and there was the further stipulation that there had to be an older susceptible child of school age in the family. In the Binghamton study children 6 months through 4 years of age were used, and in the Grand Rapids investigation the children were between the ages of 8 months and 6 years. In neither of the latter studies was it required that there be a susceptible child of school age in the household.

Table 14 is on the basis of cases per 100 person years of observation, and shows that the Binghamton results are somewhat inferior to the Grand Rapids results, but that in both of these studies

there is a significant difference in the pertussis attack rates in the control and vaccinated children, in contrast with the Cleveland study. Table 15 is on the basis of cases following household exposure, and shows the comparability of the Grand Rapids and Binghamton results in contrast with the Cleveland experience.

SUMMARY AND CONCLUSIONS

A field study of the prophylactic value of a Phase I pertussis vaccine, was conducted in Binghamton, N. Y., from January 1, 1939, to November 1, 1940. The study involved 587 vaccinated children and 699 control children, aged 6 months through 4 years. During the period of observation the pertussis attack rate was more than twice as high in the control group as in the vaccinated group, and the cases of pertussis which did occur among the vaccinated group were distinctly less

severe than those which occurred among the control children.

ACKNOWLEDGEMENTS—This study was made possible only by the generous and unselfish cooperation of so many individuals that it is impossible to give proper credit to them all. We are particularly grateful to the Michigan State Department of Health for furnishing the vaccine; to Drs. Pearl Kendrick and James A. Doull for their advice during the investigation; to Drs. Bascom Johnson, Jr., and Stafford M. Wheeler, who served during part of the study as epidemiologists; to Dr. C. J. Longstreet, Health Officer of the City of Binghamton, and Dr. Mary Ross, in charge of Binghamton's well baby clinics; to Morton Robins who helped in the statistical analyses; and to the local and state nurses and laboratory workers who helped in the investigation.

The Private Public Health Nursing Agency in the Defense Program*

KATHARINE FAVILLE, R.N., F.A.P.H.A.

Henry Street Visiting Nurse Service, New York, N. Y.

FOR many years the program of the private public health nursing agency has gone on, practically unchallenged. It has had the strong support of leading citizens. Its program has remained the same. Major changes have been few. Recently, however, public funds for support of public health have become increasingly available, not only to expand service into areas hitherto unserved, but to expand the official agency program itself. In some localities consideration is being given to the possibility of the public agency taking on the bedside nursing service—the traditional province of the private group—in order that only one nurse will serve the family. The need of a private nursing agency as a separate entity is being seriously questioned in such places.

Coupled with this shift of program comes the demand for nurses by state and federal governments; and in some of our large cities such an apparent shortage of nurses has developed that many agencies and institutions are finding it decidedly difficult to staff their units. Most nurse administrators are noticing an increasing unrest among the members of their staffs—particularly in the private agency.

In the face of this situation it is well

that we ask ourselves what the function of the private agency is today. Does it have a real contribution to make to the defense program as well as to community health, which justifies its demands on the contributor—who in addition to facing greatly increased taxes is besieged on all sides for contributions to a multitude of worthy causes? Can it justify the employment of nurses when the demand for them is so great elsewhere?

In the past we have stated our functions as follows:

1. To supplement but not duplicate the service of the official agency, working under its leadership and planning with it on a community basis. In most communities this has meant chiefly a program of bedside care, with a varying amount of health supervision of individuals or families, selected usually from a morbidity service intake.

2. To use the service for field experience for students of public health nursing. Most large private agencies have considered the preparation of students as secondary only to their community service program.

3. To study and develop new methods and services, since private administration gives flexibility to the use of funds.

4. To develop a lay public that is educated, through active participation in the service, to an appreciation of the values of public health, so that it will work for the maintenance of community service adequate both in quality and quantity.

These functions are time-honored in theory, but actual practice has seldom measured up. Too frequently we of the

* Read before the Public Health Nursing Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October, 16, 1941.

private agencies have felt that official leadership was not of a quality which deserved our coöperation, and instead of working to improve it we have sought many times to take over activities it should perform. We have only ourselves to blame if in some communities today, as the public agency has come to be more financially secure the private agency is looked upon with suspicion, as of doubtful value; and the contributions which we see ourselves able to make are regarded without great enthusiasm.

In the light of the present situation, these functions of the private agency will be discussed separately.

THE SERVICE PROGRAM

For many years the National Organization for Public Health Nursing and the American Public Health Association have stated that in any one area there is usually need for only one public and one private public health nursing agency. The defense program would seem to demand from each of us stringent economy, and to require each community to make community self-evaluation and planning its first duty. Whether the initial request for this comes from the official or the nonofficial group is of far less importance than that the effort be sincerely made. When wise leadership and professional integrity are present and agency prerogatives submerged, relative values as to service needs are readily recognized, and the precedence of basic needs over "frills" is insisted upon. Luxury service will not be allowed to absorb nursing time even though income from well invested funds is available for that purpose, until all essential professional needs are met throughout the country. The first obligation of every private agency today in the defense program, therefore, is to promote such a community study and to insure a wise, economical use of nurse power.

Our second obligation arises out of

this. Having merged our private agencies, at least, into one administrative unit in each area, we have a tremendous need to study details of service itself; and, with the health department and all other groups concerned, to determine the order of importance of service needs and how they shall be met. Such joint planning on a community basis will in most areas show that many of the unmet needs arise from a lack of just this type of community planning and can be met much more adequately with the same staff if an inclusive, over-all plan is developed. For the visiting nurse service this will mean a review of its entire intake policy in the light of local morbidity and mortality statistics, and will in most communities show a need for at least three definite developments if the community is to be well nursed and nurse power conserved.

COÖRDINATION OF HOSPITAL AND HOME CARE

First is the need to tie hospital and home nursing care together into a co-ordinated unit through carefully worked out, written coöperative agreements, by which certain types of patients will be automatically referred to the visiting nurse service with medical orders for home follow-up. In New York City a plan has been developed under the leadership of the Department of Health, which calls at present for referral of clinic patients of the following types: antepartum patients, premature infants, and those in the neonatal period, rheumatic fever patients, and other children with cardiac conditions while convalescing at home. Other types will be included as our study progresses. Under this plan the visiting nurse service makes one visit to each patient reported and on that basis selects patients most in need of further care. Its health supervision load is drawn, therefore, not alone from its morbidity service but from those types of patients for which

local vital statistics show the greatest need for service.

Since in New York City the indigent sick secure medical care largely from the hospitals and clinics, no plan for selection can be made except as hospitals and their medical directors are brought into it actively. So long as the private agency serves only those who know how to ask for care, and does not go out after the patients who most need that care, it cannot claim to be administering its service as a public health agency. The amount of free work that the various visiting nurse services throughout the country can do differs considerably, but the need for constant reëxamination of intake policies so that the free work done will best meet public health needs is evident.

CARE FOR MIDDLE-INCOME GROUP

Second, a study of the community public health nursing program will in most instances show that the middle-income group of citizens sadly lacks nursing care when ill at home. Usually they neither need nor can they afford full-time nursing service. Frequently, however, these patients do not understand the use of the part-time pay service that the visiting nurse service has to offer, and an active promotion program is needed, at least in the larger cities. This involves a carefully worked out plan with both the hospitals—the semi-private and private services—and the organized nursing groups. In New York City, we have found a great need for home care following discharge from hospitals for the semi-private group who carry hospital insurance, and who are almost entirely unknown to social service. While these patients have met their hospital costs through insurance, their medical bills often mount to a disastrous sum, and the need for guidance in budgetary planning is frequently second only to actual nursing care needs.

At the Henry Street Visiting Nurse

Service the part-pay and full-pay service in the last year has increased 30 per cent and we are making great effort to give it wide publicity and adjust administratively to its demands, in various ways, such as extending service into the evening. As might have been expected, we are finding the need for intelligent nursing as great here as in some of the less privileged homes. Care must be taken to see that this service does not encroach on the free service, however. This necessitates clear thinking by the board of directors and a recognition of two separate divisions in the budget—that for free care limited by the contributions secured for free work, and that for paid care adjusted to the fees received. Service by nurses is generalized, but growth of each service, speaking from a budgetary standpoint, is governed by different factors.

SERVICE TO INDUSTRIES

Having seen to it that the intake policies are based on an intelligent community plan, statistically guided and economically administered, the private agencies in many sections of the country will in addition be needed to supplement official efforts in safeguarding the health of the industrial worker. It is expected that the department of health will study industrial health needs and supply an advisory personnel which will assist local industries in the development of health services. In industries having defense contracts pressure is already great, the incidence of accidents and illness is increasing, and employers are eager to do all that is possible to keep employees at work. Well qualified public health nurses are needed for such services and the private agency can make a real contribution by preparing and then freeing its own staff nurses for such work. In the case of small industries that cannot afford or do not need the full-time services of a nurse, the agency can consistently sell service

on an hourly basis at cost. A number of communities have already begun to offer such a program to industry and the sale of nursing service by visiting nurse associations is slowly growing.

In New York City, with the approval of the Health Commissioner, the Henry Street Visiting Nurse Service sells such service to the plant at cost, and its nurses are finding the opportunities for health instruction so real that they are grateful for the privilege thus afforded. In addition, requests from employers for contracts with the nursing agency to care for employees when sick at home are increasing rapidly, necessitating a real effort in our staff education program to strengthen the content of our adult health supervision visits. About one thousand such contracts, either direct or through group insurance, are in force at present in the Henry Street Service.

So, in this emergency, we still adhere to our first historical function—that of supplementing but not duplicating the official agency's program; taking pride in being a necessary part of the community plan; respected, we hope, by our coworkers because our sense of values is guided by a public health knowledge of community needs, and not by agency consciousness.

PROFESSIONAL EDUCATION PROGRAM

Although at all times the private agency has afforded valuable field experience for inexperienced public health nurses, perhaps there has never been so great a need to supply it to such large numbers of new workers as there is at present. When this summer the U. S. Public Health Service decided to employ over a hundred nurses, it was the private agencies who largely furnished this personnel—and rightly so. For over the country as a whole the public agencies have need of every experienced staff member if essential community services are to be maintained. If inexperienced

nurses must be employed immediately for replacement they can probably be assimilated more rapidly and effectively by the private group with its bedside program and long experience in training than by the average public agency. Moreover, if we as a group believe in public support for health work, we should care intensely that the highest possible civil service standards be maintained, and be ready to make any sacrifice necessary to assist in recruiting a well qualified personnel.

Since defense industries and extra-cantonment zones represent the most difficult types of pioneer services, we must plan to release experienced staff members. There is no place here for the poorly adjusted, inexperienced, restless nurse, and we have as definite a responsibility to keep her from applying as we have to urge the right type of nurse to go.

At the Henry Street Visiting Nurse Service, the Nursing Committee and Board of Directors recognized this and approved a plan involving the following steps:

1. A plan was to be developed to release the maximum possible number of experienced nurses for government service and still maintain a satisfactory quality of service locally. This involved a study with each staff member of her stage of development and a mutual recognition of her individual place in the plan. It was decided that those released to the government should have had at least 3 years of supervised experience, should have completed 1 year's study in public health nursing theory, and should be mature, well adjusted, dependable workers. It was considered equally important to select those who would remain in the organization to carry the service load and continue actively with their preparation, while assisting with the induction of our increased number of trainees. It was thought that a maximum turnover of 100 such nurses could be handled each year so long as the emergency exists, which just doubles the usual rate.

2. The plan next calls for enlargement of the recruiting and staff development program so that replacement with a basically sound

young group will be assured and the quality and quantity of community service be maintained.

3. Provision of additional funds is necessary so that the community service program can be kept stable. It was recognized that an inexperienced staff nurse during her first year of service with us is only about 80 per cent as effective as a nurse in her second and third years. Therefore, every 5 seasoned nurses who leave are to be replaced with 6 new ones, with supervisory and clerical service increased in proportion. Believing that this is a real contribution to the defense program—for no program is any stronger than the caliber of its staff—the Board of Directors voted to meet this increased cost from capital funds, if necessary. Such expenditures will be separated from current running expenses, and studied as to their effect on visit costs.

It was agreed that in so far as possible, staff would be released under this plan *only* for defense purposes and to those sections of the country which, through lack of professional personnel, are themselves unable to provide workers for their increased needs. This involves discouraging our staff from taking positions with certain types of agencies which are not carrying essential services, or from going to communities where there is no conscious effort to avoid duplication and to use economically the nurses already available locally. In the first few months of this plan we have released 22 on a leave of absence for defense work, and many others regard themselves as on call.

The success of such a plan, however, depends on the complete coöperation of the entire staff, so that each member settles down, recognizes her function in the agency as a teacher of the new group and a stabilizer of the service, and accepts the necessity for growing up in public health as rapidly as possible. If quality service is to be maintained locally it means a double responsibility for each supervisor, who sometimes has to be helped to see that her contribution to the national defense program will be as great if she remains to

assist in the training program as if she herself volunteers for the greener fields that are calling. Upon the administrative group devolves the difficult problem of keeping the group steady and of maintainnig a sense of proportion. To speak realistically, however, we were faced early in 1941 with restlessness and an increased turnover anyway, and the plan described has been our answer to the question of whether we would try to guide this constructively, or have a turnover of inadequately prepared workers that upset our local service but contributed little to the total defense need. Only time can prove or disprove its wisdom.

In the discussion of any program of field experience it seems fitting to remind ourselves that the contribution which a private agency is able to make is directly related to the order which that agency has brought to its own house. For its value as an experience for new staff surely is small unless the nurses who work there see a community program functioning properly and the private agency's work effectively integrated into it. For too many years private agencies have emphasized in their training programs perfection of technic and routine methods of work, to the neglect of development of a worker who could plan for herself, possessing a sense of relative community and professional values as to what must come first in a crowded program. Too often the staff nurse saw expressed in the attitude of her administrative superiors a feeling that the official program, personnel, and performance were weak, and too seldom did she see in action a generous aggressiveness attempting to inculcate leadership where it rightfully belonged if it did not already exist there. Nurses do not learn coöperation and community planning by hearing it discussed in the classroom. Rather, they learn it by seeing it functioning in practice.

STUDY OF NEW METHODS

With a shortage of experienced public health nurses and a conviction that nurse power must be conserved for nursing needs, we face today the urgent question of the place of other workers in our program—of the practical nurse, the nurse's aide, and the slightly trained volunteer. Where and how can they be used without jeopardy to the safety of the patient? Must every visit now made by a public health nurse be a public health visit? If not, at what spot must service be picked up again by the public health nurse? Certainly, there are no definite *types* of patients who can be turned over to the nonprofessional group—such as the chronic or the convalescent patient—for we know how conditions within each family change. Because our bedside care program lends itself to such experimentation, we have a challenge to try out new ways by which we can conserve our supply of professional nursing through every possible use of other workers.

This coming winter should see us actively engaged in such studies. We must admit at the outset that our standardized picture will be greatly changed and perhaps the cost of visit increased. For if some of the routine of the visits is removed from the nurse's day, will not the remaining visits be longer and will not the time required for making contacts with physicians, for referring to social agencies, and for record-writing increase? What of the cost of supervision? No one knows the answer at present, but no one will deny both the importance of the problem and its complexity, and the necessity that the answer found shall fit correctly into our total future plan for community nursing.

EDUCATION OF THE LAY PUBLIC

In regard to our fourth historical function—that of educating a lay group to understand and support public health

programs—the present situation offers a good test of the success of our past efforts.

Because of the lay workers' control of the private agency through fund raising and actual administrative participation, we have always claimed that their opportunities to learn sound public health principles and practice were greater in the private agency than in the public agency. Today we public health nurses in private agencies can well ask ourselves what we have taught our lay committees and board members, and question how they are going to rise to the emergency that faces us. Can they pull their weight in this need for changing our pattern? Do they know and believe in good administrative practice so that in some instances they will even force our steps, when reluctant, into the paths of community coöperation? Here is our chance to learn whether we really prepared them for this broader field of community service and to evaluate our own philosophy in terms of their action.

SUMMARY

So, we maintain that for each private agency, in each community, the first step in finding its place in the defense program consists in bringing about a community evaluation of the total public health nursing program, so that we conserve our supply of personnel and are able not only to provide for present needs but to maintain high professional standards as defense programs expand.

Never were we as a group faced with a greater challenge, and our success may in great part be evidenced by the degree to which the coming months bring an actual reduction in the number of private agencies through merging of community groups. Appraisal at a future date should show that, resulting from this movement, came a strengthening of programs because of an increase in funds released for community service

through a saving in administrative costs, as well as a freeing of personnel for expansion into areas sorely in need of the public health nurse. Unfortunately, there is much more to be done than there are qualified workers available to do it, and a sound administrative policy must be developed to make the best use of every member of our profession. To attain this in practice throughout the stretch of this country is the most important job of the private as well as the public agency at present. There is no need to change fundamental pro-

fessional principles. The need is to make practice, long reluctant, more consistent with these principles.

It is time that each of us pause and remember that we are first of all public health—not agency—workers, and that as a group we stand together, regardless of the type of our employment, firm in our belief in the contribution which our profession can make to human welfare, and convinced that teamwork is more highly prized as our tool than is any skill symbolized by the time honored black bag.

Is There Need for the Fortification of Milk?*

E. V. McCOLLUM, PH.D., F.A.P.H.A.

*Professor of Biochemistry, Johns Hopkins University, School of Hygiene
and Public Health, Baltimore, Md.*

IN discussing this question it is unnecessary to dwell upon the variation in the nutritive value of milk as affected by summer and winter feeding. That there is such variation to a demonstrable degree is well known, but present-day practice in the management of dairy herds is such that the health of the cows and the flow of milk throughout lactation is rather generally maintained at good standards. There is sufficient evidence that ordinary milk as sold in cities is of uniformly good nutritive quality. The numerous experiments on animals and the dietetic studies on children in which the merits of milk as a supplemental food were demonstrated were, with few exceptions, conducted with ordinary market milk. Such studies, together with the well known fact that in the feeding of infants and young children milk is quite indispensable, have fully justified the statement that milk is the one food for which there is no effective substitute.

VALUE OF MILK IN THE DIET

With the exception of the bottle-fed infant, when milk diluted with water may for a brief period form the sole food, milk is never employed as the sole source of nutriment. The specific

contributions of milk are calcium in amounts not readily obtainable from other foods, enhancement of the biological value of the dietary proteins by reason of the high content of certain essential amino acids in milk proteins, and vitamin A and riboflavin in particular among the vitamins. Milk is the most important of the protective foods from the standpoint of improving the quality of the diets ordinarily selected by individuals in the Western Hemisphere.

The value of a generous quota of milk and other dairy products in the human diet is not so apparent in a country where people eat as wide a variety of good foods as is the custom with the majority of Americans whose economic status is satisfactory, as it is, for example, among the different racial groups of India, where lack of transportation, agricultural limitations due to soil and climate, taboos, religious principles and prejudices, have determined that large groups of people subsist upon simple and monotonous diets of very different qualities. The diets and the physical characteristics and health standards of several racial groups in India have been described by McCay, McCarrison, Aykroyd, and others. The basis of all of these diets is cereals, pulses, vegetables, fruits, and milk. Quantitatively the variation in the consumption of each of the classes of foods

* Read before the Food and Nutrition Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

of vegetable origin is great, and that of milk enormous. The poor Bengali who eats rice together with dahl (a legume seed), vegetables and oil, with a little fish, is of inferior physique. The same is true of the Madrassi, whose staple diet is rice, and who takes no food of animal origin. On the other hand, the Sikhs, the Mahratta, and the Pathan peoples are pastoral in their mode of life, and include very liberal amounts of dairy products in their diets. All of these peoples are described as of superior physical development.

The consumption of an adequate quota of milk products is imperative to make our type of diet fully adequate for the maintenance of a high standard of health. This point is especially in need of emphasis at present, when enthusiasts over fortification of foods are saying a great deal about the extent of malnutrition in the United States, and promoting the belief among the uninformed that our resources in foods presently available are not sufficient and that we need to improve various items in the dietary in order to safeguard health. The errors in eating habits of our time lie in the wrong selection of foods from among our available products. The causes are principally due to poverty or ignorance or indifference. There seem always to be some who do not want to be saved.

FORTIFICATION OF MILK WITH VITAMIN D

For many years health officials, with a view to safeguarding milk against the dangerous human contacts which may infect milk and bring about epidemics, urged the adoption of ordinances prohibiting the subtraction from or the addition of anything to market milk. This practice became general and was a great safeguard of consumers. The first relaxation of this standard of practice which occurred with the approval of organized medicine and other public

health officials was that of permitting the sale of market milk fortified with vitamin D. The advent of vitamin D milk was the result of very special conditions. After the announcement in 1922 of the discovery that there existed in certain fats and oils a vitamin which exerted an extraordinary influence on the maintenance of the normal phosphate ion content of the blood, facilitated to a remarkable degree the absorption and retention of calcium and phosphate ions, and regulated the calcification of growing bones—in other words, protected infants and children against rickets, then exceedingly common in temperate regions—the newly discovered nutrient designated vitamin D was enthusiastically proclaimed by the pediatricians. They recognized that here was a discovery of fundamental importance to the public health. Distinguished medical men at once recognized that this vitamin should be provided to all infants and children living under climatic conditions which contributed to the prevalence of rickets. It was agreed that a method for its distribution was desirable, which would insure that the largest possible number of infants and children would receive it in adequate amounts for prophylactic purposes without reliance upon a prescription by the physician or upon the solicitude of the parents to secure it through the drug store. It was generally agreed that milk was the food of choice to serve as the carrier of the vitamin. With few exceptions vitamin D milk has had the approval of health commissioners as well as of the medical profession, and it is apparent that it has come to stay. The prevention of rickets in children constitutes one of the great achievements in safeguarding the public health. It was, however, only because of the unique situation presented by the fact that vitamin D is indispensable to the protection of the health of an infant, and by the further fact that none of

our common foods contain the vitamin in sufficient amounts—facts which necessitate obtaining it from some source not readily available to the general public—that the rigid requirements of milk ordinances regarding additions to milk were relaxed.

SYNTHETIC VITAMINS

But we have recently seen astonishing development in certain of the food industries owing to the availability of low cost synthetic vitamins or concentrates made from natural products. During the past thirty years spectacular discovery followed spectacular discovery in nutritional research. Hitherto unsuspected nutrients were brought to light in rapid succession. Their absence, or their occurrence and relative abundance in each of the more common foods, was revealed by experimental studies. The nutritive needs of the body in quantitative terms as respects each of the known nutrients were studiously inquired into until we now have a most valuable body of knowledge concerning these matters. Experimental studies with many combinations of foods in different proportions revealed combinations which sustain optimum nutrition, and others which lead to impairment of the physiological status in different degrees. Such results were amazing to a generation of biochemists and physiologists who had been taught that a suitable mixture of protein, carbohydrate, and fat, together with a not well defined list of inorganic elements, would be sufficient to nourish a mammal satisfactorily during growth and throughout life. Pictures of animals suffering from specific malnutritional states dramatized the new discoveries and aroused the public interest. The deductions from animal experiments that certain human diseases which were widespread were due to dietary inadequacy—beriberi, scurvy, rickets, night-blindness, pellagra, etc.—aroused the greatest interest of both the medical

profession and the consuming public. The promise of better health through right eating was kept before the public, which became nutrition conscious to a hitherto unprecedented degree.

Discovery of the dietary properties of individual foods inevitably placed some in more, and others in less favorable positions as respects their contribution of essential nutrients to the diet. Inevitably those who sold foods for which nutritional research had facts pertinent to good sales talk played up the merits of their products in every way possible. It was good business. Those who dealt in products which science said were among the more deficient foods in essential nutrients were in low spirits, believing that their industry was being hurt, and that worse was yet to come. Time, however, brought other surprises which changed their mood to hopefulness and expectation.

As soon as a new vitamin was discovered, efforts were made to isolate it in a pure state. This accomplished, attention was turned to increasing the yield of an isolated vitamin from natural products. Soon enough of it was available for the organic chemists to apply their technic for discovering the structure of its molecule, and soon thereafter for synthesizing it. Within the past few years certain vitamins have been manufactured on a large scale and their cost has been greatly reduced. There are two great fields open for the exploitation of synthetic vitamins—through the drug trade and through their addition to foods. Both of these outlets are being vigorously promoted. Retail drug trade in vitamin preparations has now reached the proportions of big business. In the September 15, 1941, issue of *Barron's*, the national financial weekly, the following statement appeared:

Meanwhile, that busy group of companies engaged in selling vitamins to the trade, is continuing to expand sales of its product. Ten years ago, retail sales totaled around

2 million dollars a year. In 1939, the last year for which figures are obtainable, retail sales in drug stores reached 100 million dollars. Currently, they are believed to be much higher.

It appears that almost every one interested in the sale of a food which is deficient in one or more nutrients has day-dreamed about adding the missing substance with a view to increasing the sales appeal. Until quite recently they were all deterred by the high cost of synthetic vitamins and concentrates, but they are no longer too costly to warrant testing out the industrial possibilities of their addition to foods. Accordingly we are witnessing the adoption of restoration of vitamins and minerals removed in the milling of cereal products, the so-called "enrichment" of flour, and the fortification of fats and oils used in the manufacture of butter substitutes with vitamins A and D. There is some discussion of the vitaminization of sugar.

These more or less general statements about foods and nutrition were intended to be prefatory to more specific discussion of the problem of fortification of milk. They seem justified because they illustrate the movement toward "improving" deficient foods.

FORTIFICATION OF MILK

Milk is low in iron, copper, manganese, and rapidly loses its content of ascorbic acid after it leaves the cow, and contains very little of it when pasteurized. It is not, therefore, a complete food when it serves as the sole source of nutriment over a considerable period. Many inquiries have been made concerning the proposed advantages of fortifying milk in various ways such as "mineralized milk," "vitamin C milk," or milk fortified with several vitamins and inorganic elements. It has been proposed to add carotene to milk to make winter milk of the same color as that obtained from cows on green pas-

ture, and at the same time increase its potential vitamin A value. It is evident that some distributors have supposed that there may be enough sales appeal, and increased nutritive value in such so-called "improved" milk to warrant putting it on the market. At present in one city there is being distributed a milk fortified with five vitamins and certain mineral elements, and with the approval of the health department.

If we accept the view that it is easily possible to plan fully adequate diets using only natural foods, it would seem that we should do well to rely on these rather than to encourage separation of the components of cereals and then partially restore the essential nutrients removed in refining. It would also seem to be a safe conclusion that, all things considered, the fortification of vegetable fats and oils to bring them into competition with milk fats, whether in the form of fluid milk, cream, butter, or cheese, is of doubtful expediency. This is especially true from the standpoint of the farmer who produces milk. There are many vegetable foods which are so rich in carotene that when dairy products are included in the diet in amounts sufficient to supplement it in other respects, it is easy to raise the provitamin A intake to a generous allowance without making use of fortified fats in human diets. Carrots and tomatoes are examples of rich sources of carotene.

Valid reasons for discouraging the enrichment or fortification of foods with vitamins or minerals or both are, first the item of cost, and second the complications which will arise in the planning of dietaries when restored or fortified products are purchased along with natural foods. It is uneconomical to take foods apart and then recombine certain components, and it is an economic waste to include in the daily menus more than the actual requirements of any vitamin or mineral, except

under conditions when the body stores have become depleted.

The common sense view seems to warrant the conclusion that it is unwise to permit fortification of milk other than with vitamin D. It is unnecessary in the interest of the consumer and undesirable from the standpoint of the distributor. The sales value of a line of special milks, mineralized or vitaminized, is still undetermined, but it would appear that if such products are purchased by those who are adhering to wisely planned diets they will be buying something that they do not need and so spending extra money to no good purpose. It would be more advantageous for a family to buy more ordinary milk than to buy a lesser volume of so-called "improved" premium milk. Any fortified milk must be a premium product since its production will be expensive. If the sales volume of such milks remains small, or falls after being built up by advertising, as has often been the case in the past when special dairy items have been promoted, the distributor may find that he has an incubus on his hands. He cannot easily drop such items so long as even a small number of customers continue to ask for them, and the cost of preparing a few units for distribution may result in loss.

It is believed, too, that if milk distributors yield to the temptation to follow the trend of the times and put on the market fortified milk, and give it the publicity necessary to create demand, they will be doing a disservice to their customers by creating a belief that ordinary milk is not the superior food that it has been extolled to be, and that it needs doctoring to make it a desirable item for the consumer to purchase. Every nutrition authority

during the past twenty-five years has lent the influence of his reputation to the proposition that ordinary milk is a superior food and an economical purchase, that it is the best single supplementary article of diet among the protective foods.

Now to promulgate the idea that milk improved in one way or another is preferable to the natural product is misleading to the public. It will create confusion in the public mind, and in the long view is an unsound policy from any viewpoint.

No one has ever recommended that milk shall be used otherwise than as one component of an otherwise well selected diet in America. In its natural state it possesses the outstanding properties we desire as a supplemental food. It is not recommended as a source of iron, copper or manganese, or ascorbic acid, which nutrition authorities all agree should be secured from other sources. There is no advantage whatever in making any single food a complete food for all nutritional purposes. We have a great variety of appetizing foods and we will fare best by taking a variety of foods, each of which provides something which is needed.

Quite apart from any nutritional consideration, it seems undesirable to permit fortification of milk other than with vitamin D on account of the burden which such practice would put upon health officials. Constant inspection and assaying would be necessary in order to insure that such special items are what they are stated to be. If every distributor were to sell fortified milk, the burden of official supervision would become very great, while the service rendered and the expenditure involved would be of doubtful value.

PROSTITUTION IS AN AXIS PARTNER

IN the week beginning Monday, December first, we read *Plain Words About Venereal Diseases*, by Thomas Parran and R. L. Vonderlehr, respectively Surgeon General and Assistant Surgeon General of the United States Public Health Service. Also we read and listened to the repercussion and controversy which followed in the wake of this book's publication. By the end of the week we were preparing an editorial which possibly would have prolonged the argument, but the events of Sunday, December seventh, changed all this. There is now no time for deciding whether or not the Army has been lax in enforcement of the provisions of the May Act for repression of prostitution around military establishments; and neither is there time for deciding whether or not the blunt criticisms by the authors of this book were in good taste or along proper governmental channels. In the face of the present situation these matters become academic and must be thrown into the discard with other fine-point disputes which we thought we could afford when we were preparing somewhat leisurely for defense.

From here on, in matters relating to the public health, the offensive must be taken just as it must be gained in military and naval affairs. It follows then that a new hard-hitting and planned attack must be launched. In regard to venereal diseases, as they relate to the military and naval forces, the following premises, numbered one through five, appear to lead logically to the conclusion set forth below as number six.

1. The venereal diseases have always been a menace to the health and efficiency of soldiers and sailors.

2. Prostitution is the great reservoir of venereal disease.

3. Evidence at hand indicates that prostitution has been flourishing in many areas near military and naval establishments.

4. Unless some unknown and strangely protective new factor has entered into the situation, prostitution existing near naval and military establishments is a menace to the health and efficiency of the Army and Navy.

5. The May Act, signed by the President on July 11, 1941, prohibits prostitution within such reasonable distance of military or naval establishments as the Secretary of War or the

Secretary of Navy, respectively, shall determine to be needful to the efficiency, health, and welfare of the Army and Navy.

6. The May Act should be enforced quickly, effectively, and continuingly, without recriminations, hair-splitting arguments, or gloomy forebodings as to usurpation of state and local authority by the federal government.

Let's give neither aid nor comfort to the enemy.

VERTICAL VERSUS HORIZONTAL ADMINISTRATION

IT is interesting to observe that an increasing number of public health workers are becoming conscious of a need for more clearly defined administrative relationships between themselves and their coworkers, between the individual service units within their organization, and between their own organization and other organizations. Even more significant is the fact that many of those who were once unrestrained and vehement champions of one method of administration or another are now, as their programs have expanded and their responsibilities changed, willing to see some virtue in types of organizations and methods of administration which previously they had damned roundly. This developing interest and this new tolerance may be put to good use and perhaps to severe test in bringing about a just peace between the adherents of "horizontal" administration and the proponents of "vertical" organization and procedure. These quoted words, incidentally, are not good terms, but they are generally understood, and for want of better they must be used.

How best to combine the imagination and planned strategy of a technical staff with the stop-gap technics and realities of the firing line is not, of course, a new problem or one confined to public health. It is encountered in industry, in business, in the military services, in hospitals, and in fact in any situation where there is a central directing group of specialists on the one hand and on the other far-flung operations of the organization as a whole, under the immediate charge of local directors. In public health administration the objective, naturally, is to provide a smooth and untortuous channel along which the knowledge and facilities of the central organization may flow to and through local units without washing away that authority which the local director must possess if he is to perform successfully. Complete autonomy of the local units, say in the director of a city district or in a county health department, tends to inhibit the flow of technical service and advice from specialists in the central office to their corresponding specialists or technicians serving in the local units. As against this, to have special services of an operating health department, as in tuberculosis or public health nursing, directed by bureau chiefs in a central office, interferes seriously with coördination of the various activities of the local unit and makes it impossible for the director of that unit to function other than as an administrative clerk. Personalities, too, and guild consciousness of those in the many professions or near professions of public health, and even the respectable urge to do a good job of work, seem to have added confusion to this already difficult problem.

No wise man will speak ex-cathedra on this subject, and the more emphatically one argues for either complete vertical or complete horizontal administration the more likely is he to be in error. Central bureau chiefs and the services which they and their staff render are largely concerned with what to do and how to do it in their respective fields. The local director is responsible not only for insuring high

standards in what is done and in the way in which it is done, but also he is the only person in position to decide where to render local service and when and to whom, with the personnel and resources locally available. No victories are won with only staff work, be it ever so brilliant, nor with only tactical officers, be they ever so energetic. What, seemingly, is needed in public health administration is an organization and procedure which will combine provisions for central technical guidance with assurance of responsibility and authority for the local director. It is not probable that any one fixed pattern will serve all places. Wisdom appears to indicate that the best in vertical and horizontal administration be conserved, harmonized, and utilized.

THE RIM OF THE CARIBBEAN

ONE is inclined, naturally, to discourse upon his or her own recent experiences, provided they are reasonably respectable, and we claim no exception to this tendency. Having just swung around the rim of the Caribbean, we want to talk about it, not as a travelog, but rather from the standpoint of the health work being done in that area. Of course, since our progress was a somewhat rapid and centrifugal one, we are not in position to speak authoritatively or in detail, but in spite of this we did gain an impression as to the health problems and practices of some of the countries bordering on the Caribbean.

In these countries one finds still a strong and necessary interest in the fundamentals of sanitation: anti-mosquito work with all this implies for control of the various genera and species with their divergent habits and sometimes seemingly bizarre choice of breeding places; excreta disposal with the programs ranging from squat-hole type of latrines to municipal sewage plants and on to wearing-of-shoes campaigns; small and large water supplies, abattoirs, and meat markets, garbage fills of low ground, and village incinerators—all loom large in these intensive and widespread sanitary programs. Superimposed on such fundamentals are efforts to carry on the more or less conventional public health activities seen in a more or less conventional health department in the United States. And over and above these things are to be seen services which reflect local problems: research and field work in schistosomiasis, in dysentery, in hookworm, in production of anti-venom serum; the far-flung listening posts of yellow fever control, made up of viscerotomy services in Venezuela, Colombia, and Panama; the undertakings to meet problems arising from the establishment of the defense bases of the United States in some of these countries.

One sees, too, on most of the rim of the Caribbean, strongly centralized health departments, where complete authority and financial responsibility rest with the central government. The director of the national or federal division of tuberculosis or maternal hygiene, for instance, is not found in an administrative office, but in a clinic rendering direct service to citizens who live near the seat of government. This, of course, strikes a North American visitor as unusual. One is inclined to wonder if a federal chief of service, so preoccupied in direct local activities, can possibly have time for or an interest in the complex problem of providing that service on a nation-wide scale. Yet this close touch of chiefs with the realities of action is refreshing, and certainly is not to be criticised merely because it is strange. In some of these countries, but not all, serious attempts have been made to extend public health work through a health unit system. Quite in contrast to North

American sequences and associations, many such units have come into existence by being engrafted upon an already existing dispensary service or are the result of the pulling together, locally of special diverse services of a federal department of health which previously had operated independently of each other in that locality.

Unfortunately, in Caribbean countries, few medical men have made public health work a career. The physician who enters the health service, in most instances regards his term of office as temporary, and this attitude is shared by his colleagues and the governmental authorities. Though a number of men have received postgraduate instruction in public health, full-time service is unusual. Perhaps if, in the matter of career work, the United States had set a better example, it would have benefited the health services of these countries to the south of us. But let it not be imagined that the flow of public health knowledge must necessarily be from north to south. There is an enthusiasm, an energy, and a realism in the public health work of the Caribbean from which North Americans may well profit.

Credit Lines

A Selective Digest of Diversified Health Interests

D. B. ARMSTRONG, M.D., AND JOHN LENTZ, M.S.

WHAT'S THE USE?

These are unhappy times—"times that try men's souls." It is only natural that many of us who heretofore have taken pride in our work and have drawn spiritual sustenance from it, are suddenly asking ourselves: "What's the use?" When war came, we were in the midst of a manuscript dealing with the history of a great experiment in life conservation. At once we felt that this, as well as other undertakings of ours, were innocuous projects having no relevancy to the present scene: the here and the now. We thought, too, of "Credit Lines." Futile to continue it, we felt. What difference does it make whether health pamphlets are excellently written and attractively illustrated? Who cares now whether our posters are nicely designed and competently executed? Then we looked about us and sensed what it would mean if everyone surrendered to bafflement or lost himself in emotional flight. Gradually, we realized that it was unthinkable to surrender to a "what's-the-use" philosophy in times like these. There are many urgent problems in the offing that health workers must solve, and until these new problems challenge us, it is best to continue with the tasks at home. There will be new and special opportunities for service in every phase of public health as long as our country is em-

battled. Let us be ready to give our best to the difficult and complicated jobs that may be ours to do, so that in the end we may have the satisfaction of knowing that health personnel shared in the triumph of a wise and provident society over one of decadence and perversion.

What's the use? Plenty!

A DAY OF HEALTH EDUCATION

Approximately 100 health educators representing the official and voluntary health, medical, and social agencies in the New York City area attended the second annual one day Health Education Conference, held under the auspices of the New York Academy of Medicine, on November 8, 1941. The program centered around the theme of directing attention to the objectives of health education and the methods and technics best suited to accomplish these objectives. Four very stimulating and enlightening papers were presented that brought out many new concepts regarding the general theme of the meeting.

Dr. Edward J. Stieglitz, of the National Institute of Health, read a paper on "The Rôle of Health Education in Present-Day Medicine" that was a very scholarly analysis of the individual's responsibility for his continued health and of the pressing problems of senescence. Dr. Stieglitz emphasized that health is more than absence of disease and that, although there is no such thing as perfect health, it is an ideal to be approached as nearly as possible. He

Please address samples of printed matter, comments, or other editorial contributions to the editors at One Madison Avenue, New York, N. Y.

stated that the measurement of health is individual, not general, and involves the prediction of future physical fitness as well as the attainment of present fitness. Dr Stieglitz pointed out that there are two types of preventive medicine, wholesale and retail, the wholesale being the activities of public health dealing with the prevention of exogenous injury, the retail dealing with the maintenance of individual health. The wholesale type has now advanced to a point where the public is protected from many infections through a safe environment and immunization. It is effective mainly without the efforts of the recipient and has affected largely the diseases of youth.

In the retail type of preventive medicine, Dr. Stieglitz maintained that the pediatricians have been the principal leaders, but little advance has been made with the degenerative disorders of old age. The retail method requires health inventories which are much more than routine physical examinations. These inventories involve expense, skillful examiners, and intimacy. They must be voluntary and they require initiative on the part of the individual. Physicians as well as the public must be educated to further advances in the field of health inventories, Dr. Stieglitz said.

Another interesting section of Dr. Stieglitz's paper brought out the fact that no disease can be considered to have but one cause. Etiology was divided into three factors: predisposing, provoking, and perpetuating. The attack against many diseases must be primarily against the predisposing rather than the provoking cause, and the perpetuating must also receive serious attention. The advancing age distribution of the population has caused a shift in the character of the principal diseases from infectious to degenerative. Gerontology, the science of the process of aging, has become an important study and introduces not only new clinical problems but socio-

economic problems which demand the coöperation of workers in many fields allied to medicine. The speaker said that at present we cannot hope to add many more years to life, but we can add more life to the years and make longevity a blessing rather than a burden. Man should become, like Oliver Wendell Holmes's "Wonderful One Horse Shay," a well balanced machine in perfect operation until the end. This will make man useful to society in his years of maturity and good judgment, rather than a burden on the shoulders of youth.

Two important points which Dr. Stieglitz particularly stressed were the necessity for increased accuracy in lay medical writing and the pressing need for well adult clinics where information regarding nutrition and endocrine disturbances, among other things, could be obtained.

Selskar M. Gunn, Vice-President of the Rockefeller Foundation, who is now engaged on a project for the National Health Council, spoke to the conference about an experiment in education in rural China in which specialists in social, economic, agricultural, and medical fields were brought together, how barriers between them were broken down, and how they were taken into the field to see their common problems and work out methods for their solution. Thus started on a sound basis, even war and the migration of refugees could not stop the experiment. Mr. Gunn expressed the belief that in the United States socio-economic problems and health problems must likewise be dealt with, as they are inseparable. In attacking a problem, the Chinese first go into the field, learn the facts, then apply the educational technics needed. It was felt that we in this country could avoid a great deal of fumbling if we would first take time to get at the basic facts. Facts first, technics later.

A paper, Psychological Barriers in

Health Education, was read by Edward L. Bernays, well known public relations consultant. This paper stemmed from a study which the author made of health education in the United States at present. He drew a rather scathing picture of what he considered wastefulness in health activities because of lack of coordination. Mr. Bernays pointed out that the barriers to health education are both psychological and physical. The psychological barriers involve the attitudes of health educators, who often are not very efficient, and the attitudes of that part of the public that resents the doctor when well and that is bound down by ignorance, habits, taboos, and prejudices. The physical barriers, according to the speaker, include inadequate budgets, lack of coordination, conflicting claims made in health information published by various agencies, materials that are out of date, etc. Mr. Bernays recommended that a voluntary National Council of Health Educators be formed by all health education groups to pool resources, prevent duplication of effort and needless expenditure of money and to maintain continuing research and evaluation of technics in health education.

Dr. Allen W. Freeman, of Johns Hopkins School of Hygiene and Public Health, gave a direct and forceful paper on Health Education by the Private Practitioner, the Voluntary Agency, and the Department of Health. He maintained that health education cannot become a major part of the practitioner's activity as long as the doctor's bread and butter depends upon his practice, but that it could become a more important part of his practice if he were given the proper point of view in medical school and if it were made easier for him in his practice to educate his patients. Dr. Freeman pointed to the important contributions made to health education by voluntary agencies. He felt that they had been most ingenious in developing

methods and in carrying on continuing programs of education. Departments of health, the speaker said, vary greatly in their health education activities — the large cities requiring much more organization than small rural counties. In the latter, health education must be the duty of the health officer, the nurse, the sanitation officer, and even the clerk. The nurse was termed the health educator *par excellence*. Proof of this has been revealed by studies which have shown that the nurse, visiting prenatal patients in the home, carries out more effective teaching methods than some of the best prenatal clinics.

The formal papers were followed by round table discussions, and a general summary of the day's proceedings was excellently outlined by Dr. Henry E. Meleney, of the New York University College of Medicine.

The New York Academy of Medicine and its Committee on Medical Information deserve the thanks and appreciation of all in attendance at this helpful conference.

WELCOME ALLIES

During this time of national emergency, public health personnel is demonstrating more than ever its leadership in democratic procedures by participating in many activities which have a bearing on the health of the nation. The number of professional groups which have something to contribute to the science of healthful living is becoming more and more striking. The National Association for Nursery Education held its Ninth Biennial Conference in Detroit during October, 1941, and the field of public health was well represented through physicians and pediatricians, educators, and welfare workers. The theme of the Conference "Life, Liberty, and Happiness for Children NOW" was and will continue to be of vital concern because emergency measures have made it more necessary than

ever to provide suitable care for the preschool child. The English and the Canadians have given us through their experience numerous reasons why early childhood education is essential to any national program. It is the children who must carry on, and the preschool years are vitally important because of the influence that they bear on the growth and development of a healthy people. A healthy start in life, both mental and physical, is the birthright of every child. Take notice of these nursery school directors and teachers. They need your guidance, and in turn they have much to give which has a bearing on the public health.

HAVE YOU SEEN . . .

Any issues of the Club Talk Series issued by the Medical Society of the State of New York?

These "talks" are designed to be presented by a lay person at club meetings or they may be used as publicity releases or as radio material. The Series covers a varied list of topics, two of the latest dealing with fear (as a factor in mental health) and with cancer (in which facts about the disease are set forth for school groups). We recommend this series of "talks"—they are replete with sound, fundamental information presented in a popular, appealing manner. If interested, write to the Society at 292 Madison Avenue, New York, N. Y.

The venereal disease pamphlets published by the Massachusetts Society for Social Hygiene, Inc.? (Address 1146 Little Building, Boston, Mass.)

Two publications on gonorrhea and syphilis issued by the Society are especially commendable. One is addressed specifically to the man in uniform and stresses this fact: Here are two diseases you *don't* have to have. The text is straightforward, employing terms and

phrases that are used in man-to-man discussions on this subject. The second booklet describes syphilis and gonorrhea as "saboteurs of our national defense." It is likewise a straight-from-the-shoulder exposition in which prostitution, the road house and the tavern are discussed. The two booklets are attractively executed. They bear none of the earmarks of hastily prepared "handouts," which is more than can be said for some of the publications on the subject that have recently been issued for the man in uniform.

Any issues of "Your Health," a bulletin published by the Newton, Mass., Health Department?

This health department is doing an outstanding job in publicizing its services in the community it serves. A recent issue was devoted to the prevention of communicable disease. Immunization procedures were summarized and other methods of prevention were listed and briefly discussed. This is one of the best health bulletins for "home consumption" that reaches our desk.

The fourth booklet in the Workers' Health Series?

"Clara gives BENZOL the run around" is the title. This booklet is a clear concise statement regarding the effects of benzol poisoning and preventive measures that must be taken to avoid it. The text, as is characteristic of other booklets in this Series, is appropriately written for workmen. Available from the Superintendent of Documents, Washington, D. C. Price, 5 cents.

Volume I, Number I of the National Foundation News?

This four page publication, which follows the newspaper format in layout, is to be issued monthly by the National Foundation for Infantile Paralysis, Inc., for its chapter officers and members

throughout the United States and its possessions. The publication is decidedly "newsy" in tone, reflecting activities of the Foundation in the fields of research, epidemic aid, and education. The initial volume leads us to believe that this publication will soon have a wide circle of interested readers in public health.

The reprint from the American Journal of Public Health of the Proceedings of the Nineteenth Annual Conference of the Milbank Memorial Fund?

Readers who are familiar with this excellent series of papers will surely welcome a bound copy of this material for reference and library purposes. Write to the Fund, 40 Wall Street, New York, N. Y., for copies.

A POSTER PLEA

On more than one occasion, we have "had our say" about so-called modernistic technics and design as applied to health posters. A recent communication to the editor of a popular magazine reveals that there are others who share our general feeling—to wit:

"When I was in New York a while ago I went to an exhibition called Posters for Defense. . . . I am sending you a leaflet from that exhibition. . . . I would like to ask you if you don't think there is something wrong about these posters that are supposed to make a hundred million people feel like defending democracy.

"So many of these posters are machine-like and cold, and so many of them make people look like robots and caricatures. I think I can appreciate the skill and talent that have gone into these posters, but I wonder if skill and talent are enough, all alone, with so little warm human quality to move the man in the street. Maybe abstract design can arouse emotional response in the connoisseur, but can it make the average housewife save her dimes for defense stamps or persuade a mechanic to enlist in the Air Corps? I want your opinion. I would like to know if you don't agree that posters which hope to symbolize the aims of democracy should represent their themes in human, understandable words and pictures, and not in designs that suggest the mechanistic,

unsentimental and regimented things we're fighting."

The editor agreed 100 per cent with his correspondent and added: "Let the government put in a hurry call for such human artists as Steichen, Norman Rockwell, etc., men who see with their hearts as well as their eyes."

To which we add: Artists designing health posters—PLEASE NOTE. The comments quoted above apply as well to health posters as to defense posters.

MAGAZINE ARTICLES

"Middle Age Jitters." Raymond G. Fuller. *Cosmopolitan*. December, 1941.

"How to Choose a Doctor." Robert D. Potter. *Good Housekeeping Magazine*. November, 1941.

"The Truth About Caesareans." Maxine Davis. *Good Housekeeping Magazine*. November, 1941.

"How Much Do You Know About Heredity." Amram Scheinfeld. *Ladies Home Journal*. November, 1941.

"The Danger of Nervous Fatigue." Edward Spencer Cowles, M.D. *Good Housekeeping Magazine*. December, 1941.

"Eating for Oomph!" William L. Laurence. *Ladies Home Journal*, December, 1941.

"Was I Dreaming?" Gretta Palmer. *Ladies Home Journal*. December, 1941.

"The Great American Stomach." *Fortune*. December, 1941.

"Sister Kenny vs. Infantile Paralysis." Lois Mattox Miller. *Readers Digest*. December, 1941.

"These Millions Need Not Die." Paul de Kruif. *Readers Digest*. December, 1941.

"Too Much Surgery?" Miles Atkinson, M.D. *The American Mercury*. December, 1941.

JOTTINGS

The request for slogans in the October issue of "Credit Lines" prompted readers to submit the following: All for

Health and Health for All, A Healthy Nation is a Wealthy Nation, Public Health for Public Happiness. Let's have more suggestions. . . . Letterheads can be used to spread health information, as demonstrated by the Newark, New Jersey, Department of Health. The official stationery of the department carries the following message: "Pneumonia Picture: sudden onset, pain in chest, high temperature and chills, shortness of breath, cough and rusty sputum. Call the doctor immediately." . . . Now that the long winter evenings are here, there should be time to read those books you've put aside for leisurely(?) hours. Be sure to include on your list *The Man Who Lived for Tomorrow* (the biography of William Hallock Park), *The Doctors Mayo*, and *William Henry Welch and the Heroic Age of American Medicine*. These are outstanding books—books to chew and digest, not merely to taste and to swallow. . . . Nutritionists have long insisted upon informative labeling of food products. Here's an example of the nth degree of informative labeling displayed in a restaurant: "Hard boiled egg—1 cent; wear and tear on chicken—3 cents; rooster's fee—1 cent; total cost—5 cents." . . . The book department of a large metropolitan store recently was puzzled over the poor sale of one of the year's finest cook books entitled "100 Ways to Please Your Husband." Good cook books always sell well and the merchandising manager wondered what was holding this one down. One of the sales girls suggested that the books be removed

from the cook book counter and placed on display in the medical and health book section. The suggestion was followed. Result: "100 Ways to Please Your Husband" was sold out on short order. . . . The Greater New York Safety Council advises all motorists approaching grade crossings: "STOP, LOOK, LISTEN, and LIVE! Don't depend on the watchman—or even the gates. Train the mind to mind the train!" . . . We understand that Sister Kenny, although not present in person, largely dominated the discussions on therapy at the 1941 annual meeting of the National Foundation for Infantile Paralysis. It seems to be generally agreed that Sister Kenny's procedures are a revolutionary contribution to the treatment of acute poliomyelitis. . . . Translating scientific material into the tongue of common communication is difficult and the work that some popular writers have done in this connection is to be admired. However, when certain vitamins are referred to as "wham" and "oomph" vitamins, it seems to us that popularization is being carried a bit too far. . . . The Pennsylvania State Department of Health has produced a film for lay audiences on pneumonia, stressing the general rules of prevention and treatment, including home nursing care. . . . The National Foundation for Infantile Paralysis has produced a one reel sound motion picture for lay audiences on the epidemiology and treatment of poliomyelitis. We believe the film will be available in both 35 and 16mm. prints.

BOOKS AND REPORTS

Handbook of Communicable Diseases—By *Franklin H. Top and Collaborators*. St. Louis: Mosby, 1941. 682 pp. Price, \$7.50.

Out of the rich and interesting experience of the Herman Kiefer Hospital and the Detroit Department of Health has come this new manual. The first section presents a brief and general consideration of infection and immunity, of epidemiology, of regulations for control, of specific immunizing procedures, of serum sickness, and of nursing techniques in the home and in the hospital. Then follows a detailed text on each of the communicable and infectious diseases, presented under the following topical headings: Definition, History, Infectious Agent, Epidemiology, Immunology, Pathology, Symptoms, Types, Complications, Differential Diagnosis, Prognosis, Treatment, Nursing Care, Prevention, and References. The clinical descriptions are supplemented by 73 half-tone and 10 colored plates. In the appendix are tables showing the associated conditions, complications, and final diagnoses for several thousand admissions to the Herman Kiefer Hospital; treatment schedules for syphilis and rabies; the Detroit communicable disease regulations; a glossary of technical terms.

The book is a convenient compendium for health officers, internes, medical students, and nurses. Because of the necessarily brief space allotted to each disease, it is of an elementary rather than of an advanced character. Not only does the book have merit in keeping pace with the advances of medical science, but the author and his collaborators are equally competent in

discussing both the clinical and public health aspects of these diseases. The book is distinctive in the balance achieved between prevention and medical care. KENNETH F. MAXCY, M.D.

The Story of Clinical Pulmonary Tuberculosis—By *Lawrason Brown*. Baltimore: Williams & Wilkins, 1941. 411 pp. Price, \$2.75.

This posthumous book (Brown died in 1937) is much more than a story of clinical pulmonary tuberculosis. The three chapters: The Visit in 1700, The Visit in 1800, and the Visit in 1900 are artistically drawn pictures of the diagnosis and treatment with a rich background of the contemporary scene of life. There are chapters under the heading of Diagnosis of Early Tuberculosis, including Laennec and His Successors, Early Publications in Germany and Austria, Diffusion of Knowledge in England, Diagnosis in America. About 100 pages are devoted to the story of Modern Surgical Treatment of Pulmonary Tuberculosis. Under Some Side-lights of Importance, we find chapters on Laennec and His Writings, The Story of the Stethoscope and Early Medical Journals. Homer L. Sampson wrote a chapter on Diagnosis by X-rays and Edward W. Archibald a chapter on the Development of Surgical Methods in Treatment.

Brown, who was one of the most outstanding men of his time in clinical tuberculosis, failed to mention his own contributions to the story, though we find reference to them in Sampson's chapter. The author had personal acquaintance with many of the leaders in his field both in this country and

abroad; indeed he had many friends among them. He was a scholar and a student of history, particularly the history of medicine. His lectures on the history of tuberculosis given to post-graduate students at the Trudeau School were highly appreciated. Thus this book is not a compilation of *ad hoc* readings but the result of intimate knowledge acquired by many ways during long years.

The historical events Brown presents are always interesting because they are connected as phases of a development. The style has grace and color. The chapters by Sampson and Archibald are informative and interesting. The book might be enjoyed by persons who are interested in the development of the science and art of medicine, regardless of their field of work.

JULES FREUND, M.D.

The Premature Infant (Its Medical and Nursing Care)—By Julius H. Hess, M.D., and Evelyn C. Lundeen, R.N. Philadelphia: Lippincott, 1941. 317 pp., 74 ill. Price, \$3.50.

The development by the authors of a large central station for the care of premature infants in the Michael Reese Hospital in Chicago has permitted organization of a highly specialized system of medical and nursing care. This book contains a detailed description of this system, stressing the particular problems of transportation of premature infants to the central station, of their segregation from other infants, of control of the temperature and oxygen content of the environmental air in the Hess oxygen unit, of furnishing a supply of human milk, and, finally, of providing adequate amounts of highly skilled nursing care.

A critical evaluation of alternative methods, for example, of artificial feeding, of oxygen therapy, or control of environmental temperature and humidity is not furnished. Furthermore, the

bibliography is inadequate for a reader interested in learning the details of these alternative methods from the literature.

The discussions of physiology, of growth and development, the factors causing prematurity, are not of the same caliber as the chapters on medical and nursing care.

The book is, then, a good exposition of the subject indicated in the subtitle—medical and nursing care (of the premature infant)—in the light of the authors' experience. Because the latter has been so extensive, the book is a valuable contribution and can serve as a guide for physicians and nurses who attend these infants and for administrators interested in setting up comprehensive plans for their care.

HARRY GORDON, M.D.

Sanitary Engineering—By Harry G. Payrow. Scranton: International Textbook Company, 1941. 482 pp. Price, \$4.00.

While the general field of sanitary engineering has in comparatively recent years expanded to cover a large number of activities relating to community health and welfare, this textbook covers only those subjects which were the original conception of this branch of engineering, viz., water supply, sewerage, and water and sewage treatment. The subjects covered include hydraulics of water supply, stream flow (methods of measurement and hydrology), reservoirs and dams, ground water, water consumption, water intakes and distribution systems, pumping water, water treatment, quantity of sewage and storm water, sewerage systems, characteristics of sewage, sewage disposal and treatment, sedimentation and chemical precipitation, oxidizing processes, sludge treatment and disposal, miscellaneous treatments and sewage plant operation. The book should serve the author's announced intention that the text be used in an introductory course for sani-

tary engineers and to give civil and chemical engineers a glimpse of the problems involved in these branches of sanitary engineering. F. J. MAIER

Delinquency Control—By Lowell Juillard Carr. New York: Harper, 1941. 447 pp. Price, \$3.50.

This book represents a fresh and vigorous treatment of an old sore-spot. As director of the Michigan Child Guidance Institute, the author knows what should and can be done, and he believes that, under informed leadership, juvenile delinquency can be materially reduced.

The limited measures in force today are still on a "myth-minded" level, and Dr. Carr cites examples to show how often complex matters are approached from the side of intuition and impulse. He maintains that modern skills must be applied to personal counseling, the elimination of blighted areas in the community structure, and the rejuvenation of organizations that fail, under present conditions, to reach youth who need help.

His analysis of social breakdown and personality conflicts is bolstered with pertinent statistics and challengingly set forth. The technics prevailing in our correctional institutions, probation departments and school systems are considered and found wanting in the face of an estimated 9,000,000 handicapped children under 18 in "high-risk" situations in the United States. School teachers fall short in the timely detection of emotional difficulties, courts do not consistently sift out the most hopeful prospects for probation, and probation itself too frequently degenerates into little more than a bookkeeping procedure.

Since conventional methods have not produced any appreciable decrease in delinquency, the author urges lay participation in the campaign, as in the coördinating council movement which

started in California in the early 1930's, and has spread across the country, with organizations built around social agencies and dependable lay individuals in the community.

In his final chapter Dr. Carr describes the Michigan Child Guidance Institute, established in 1937 under the University of Michigan, and furnishing advisory services and personnel to communities which, under this direction, assume responsibility through their existing agencies for action on their own problems. Despite the niggardly appropriations voted by the legislature for this valuable work, local results thus far have been encouraging.

As an advanced textbook in juvenile delinquency, a review for those who need a "refresher" and a guide to anyone seeking practical suggestions that have vision but are not visionary, this volume should bring inspiration. To those whose primary interest is in public health it will prove doubly significant as demonstrating that the public health concept—not treatment alone but also control and prevention—applies with equal force in the field of delinquency.

AUSTIN H. MACCORMICK and
WILLIAM H. KINNEY

Orientation in School Health—By Clair V. Langton, Dr.P.H. New York: Harper, 1941. 680 pp. Price, \$3.00.

After turning the pages—there are over 600 of them—from stem to stern and reading much, I emerged with a very satisfying feeling.

This is a textbook primarily for teachers and teachers in training. All prospective teachers ought to be familiar with it. It is fair and temperate. It was written to emphasize points in the school health field that have not been adequately stressed partly because they have not been readily available. Deliberately omitted are chapters on what health material to teach elementary

school children and how to teach. Physical education is also left out because these two subjects are believed to have been quite adequately covered elsewhere.

The author is also aiming at another group for he states that experience, training, and education have not given the educational administrator "a clear insight into what health is; how it may be obtained; and still less, *how* this work may be organized in the school."

The chapters are up to the minute. School health service is excellently covered. In addition to the control of disease in general, there are rich chapters on Nutrition, Oral Hygiene, and Tuberculosis. Evidently a long road has been traveled in the last 20 years in the lighting of school buildings. Sanitation and Planning of the school plant, including ventilation, is a practical chapter. The health of the teacher is given some attention.

References are plentiful, many from reports of committees of the A.P.H.A.

This book ought to help bring departments of education and public health closer together.

GEORGE T. PALMER, DR.P.H.

The Control of Tuberculosis in the United States—By Philip P. Jacobs, Ph.D. (rev. ed.) New York: National Tuberculosis Association, 1940. 387 pp. Price, \$2.00.

The 1940 edition of *The Control of Tuberculosis in the United States* by the late Dr. Philip P. Jacobs should be read by every physician and worker interested in public health or in socio-economic problems relating to health. Moreover, every health and medical-social worker would profit by having a copy available for ready reference. Not only has there been an appreciable increase in our knowledge of the public health and social aspects of tuberculosis since the publication of the 1932 edition of this book, but there have been paral-

lel development and improvement in administrative methods and technics which the author has included in this new edition.

Clinical tuberculosis in an individual is but a symptom of a community public health and economic problem. This book not only deals with the fundamentals in community organization and administration to meet the tuberculosis problem but, by reviewing the newer epidemiological or control measures, the author reveals new areas of administrative possibilities. Whether one's primary interest is concerned with the difficulties of organizing a public health program to meet community needs, or whether it is concerned with the administrative policies and procedures which would be conducive to sound public health education, economical and productive case finding, or circumstances related to the domiciliary control of the disease (especially as it may be related to public health nursing), this volume provides the key for solving these and similar problems. Moreover, the references selected and recommended by the author provide an excellent index of authoritative data and material pertinent to the many details of the tuberculosis problem.

In view of the declining tuberculosis death rate, the chapters on case finding and tuberculosis control, in particular, deserve to be read and reread. Not only does the text of these chapters contain many important and pointed statements, but throughout each chapter may be found a description of many current policies of organization and administration.

ROBERT E. PLUNKETT, M.D.

Medical Work of the Knights Hospitallers of Saint John of Jerusalem — By Edgar Erskine Hume. Baltimore: Johns Hopkins Press, 1940. 371 pp. Price, \$3.00.

The historically-curious will be glad to see this story, first printed in three

numbers of the *Bulletin of the Institute of the History of Medicine* in 1938, now available in book form—for this is the only account in English of the work of these famous hospitallers. Organized in the 11th century they have fought their way across land and sea through the centuries protecting crusaders in medieval days or Spanish refugees today—any and all who needed help. Their hospitals in Rhodes and Malta were models for all the world to follow and even in World War II one of their ambulance units was the first to come to the aid of the victims of The Athenia who were brought into Galway Harbor.

Dr. Hume's story is well told—and not essentially interrupted by the wealth of documentary support he gives the text. There are 130 figures.

LEONA BAUMGARTNER, M.D.

Americans Live Longer!—By W. W. Bauer, M.D. Indianapolis: Bobbs Merrill, 1940. 219 pp. Price, \$2.00.

In the first chapter of this refreshing book, the author reviews simply and clearly the accomplishments of medicine and public health that are contributing to longer and healthier lives for American people. The remainder of the book is a direct message to the person who has attained middle age with a desire to live to expectancy either without prematurely developing those afflictions of middle and older life or with a wish to live happily with his unpreventable health handicap.

Commonest causes of premature crippling and death after middle age, namely, heart disease, hypertension, glandular disturbances, cancer, diabetes, arthritis, and poor personal hygiene, are described in simple physiological terms. Emphasis is placed upon early signs of trouble and methods of preventing such trouble. The final chapter, A Philosophy of Health, should be read by everyone who has attained the age of forty and is looking for a pattern of behavior that

will carry him happily and healthfully through the years ahead.

The book is especially recommended to the specialist in geriatrics, to the clinician who is adviser to middle and older aged patients and to the public health man interested in the prolongation of life and prevention of health accidents in our aging population.

CHARLES E. SHEPARD, M.D.

Personal Hygiene Applied—By Jesse Feiring Williams, M.D. (7th ed.) Philadelphia: Saunders, 1941. 491 pp. Price \$2.50.

Two major difficulties attend the teaching of hygiene to college students. Most of these young people find it difficult to apply the principles of hygiene to their own and to community problems because of inadequate background in physical and social science. Most of them also have not acquired a point of view—a philosophy of living—that includes a consideration of positive health.

It is appropriate therefore that the author who has had many years of experience in teaching college students should emphasize in this seventh edition of his textbook five chapters developing a point of view, a *sine qua non*, for healthful living. The remainder of the book is devoted to the facts of anatomy, physiology, and bacteriology essential to an understanding of personal hygiene and an application of these facts to health problems of the individual. Although community health problems are touched upon throughout the book, no special reference is made to this subject.

There has been considerable revision in this edition which adds to orderliness of presentation. More space is devoted to mental components of physical health. There is a new section on vitamins, a new chapter on prevention of specific disease, a rewritten chapter on the endocrines, and an extension of material on human heredity. Teachers of college hygiene who are using this book as a

text will find the new edition a distinct improvement because its presentation is simpler and more orderly than former editions. Some may prefer to present the factual material in the latter chapters as an introduction to the philosophies expressed in earlier chapters. A carefully selected bibliography of recent publications at the end of each section will be found helpful for class discussion.

CHARLES E. SHEPARD, M.D.

Biology of the Laboratory Mouse
—*Edited by George D. Snell. Philadelphia: Blakiston, 1941. 497 pp. Price, \$7.00.*

This book is the result of the combined efforts of nine investigators to bring together a large part of the available information concerning the mouse. Much of the information assembled was scattered so widely through scientific journals devoted largely to special fields as to have made it available only with difficulty to individual investigators. The book was written for research workers, particularly for those interested in genetics, tumors, and infectious diseases. As it has been put aptly by the editor it "presents a vertical cross-section of biological knowledge rather than the more usual horizontal cross-section" and deals with the mouse alone.

The text is divided into thirteen chapters dealing with embryology, reproduction, histology, spontaneous neoplasms, gene and chromosome mutations, the genetics of spontaneous tumor formation, the genetics of tumor transplantation, endocrine secretion and tumor formation, the milk influence in tumor formation, inbred and hybrid animals and their value in research, parasites, infectious diseases of mice, and care and recording methods.

The book should be of considerable value to research workers who use mice as part of their experimental material.

FRANK L. HORSFALL, JR., M.D.

Rheumatic Fever in New Haven—
By John R. Paul, M.D. New York: Milbank Memorial Fund, 1941. 176 pp. Price, \$1.00.

Those who have followed Dr. Paul's studies in rheumatic fever (*A.J.P.H.*, Vol. 31, Page 611, June, 1941, and elsewhere) will be interested to see how he has brought to bear on the problems of one city our knowledge about this disease, using relatively new methods which he describes as "familial epidemiology, community epidemiology, and city epidemiology." Dr. Paul presents a picture of the clinical epidemiology of this chronic and acute systemic affection of protean nature which, as he points out, is a disease of childhood, a crowd disease, and commonest in temperate climates among urban people. It is fortunate that today's student of this disease can have this study to round out those of Perry and Roberts in England, of Maddox in Australia, of Clarke in Dublin, and of Hedley in Philadelphia. This study emphasizes the clinical aspects in relationship to the epidemiology of the disease rather than the statistical approach which has characterized many of the other studies.

Dr. Paul and the Milbank Memorial Fund are to be congratulated on this study which is unique in its field. The continuing influence of Edgar Sydenstricker, who had a long-standing interest in these studies, will be apparent to the reader.

R. M. ATWATER, M.D.

Fatal Partners: War and Disease
—By Ralph H. Major, M.D. New York: Doubleday, Doran, 1941. 342 pp. Price, \$3.50.

This otherwise brilliant, extremely interesting and important volume is marred for me by a tiny fault, not due to Dr. Major. This is the publisher's use, as the symbol for medicine, of the winged staff of Hermes, messenger of the gods and patron of commerce,

thieves, and prostitutes. The symbol of medicine is the staff of Aesculapius, a cane with a single coiled serpent. That the United States Army makes the same mistake is no reason why people who could know better should do likewise. One purpose of Dr. Major's superb historical survey is to show that armies still can learn much from medicine.

Dr. Major, Professor of Internal Medicine at the University of Kansas since 1921, has much experience and skill in popularization of practical medicine, as exemplified in his earlier volumes, *Disease and Destiny* and *The Doctor Explains*. The ease with which *Fatal Partners* may be read gives little indication of the laborious care in assuring the accuracy of its detail and the artistic development of its story.

Dr. Major, like a modern Homer, tells simply but challengingly the long story of the relation between war and disease, from the epidemic factors contributing to the downfall of ancient Greece and Rome, through the pestilential imbecility of the Crusades, the swashbuckling venereal warfare of the Renaissance, the hideousness of the Thirty Years' Total War, Baron Larrey's pitiful efforts to mitigate the sufferings of Napoleon's loyal followers, the self-sacrificing care of the wounded by Florence Nightingale, the reaction to the horrors of Solferino which led to Jean Henri Dunant's organization of the Red Cross, our own ridiculous "Manifest Destiny," the only decent achievement of which was to teach us how to control typhoid and yellow fevers, the deliberate reversal by the Japanese in the Russo-Japanese War of the usual four to one ratio of death from disease to death from fighting, to the tragedy of World War I, and the present. It is a fascinating and thought provoking story.

Firmly Dr. Major insists that war itself has contributed nothing to medicine. During war physicians continue their merciful service to the best of their

ability. The best that war provides them in return is a vast laboratory in which to study the practical effects of whatever applications of their knowledge may be made. One of the greatest contributions to medicine, however, has come from that often misunderstood instrument, the United States Army. The Army Medical Library remains the most comprehensive and efficient repository of knowledge useful in medicine in the whole world. Perhaps, as a result of the present emergency, it will receive the fireproof building and full support it deserves. American physicians might help by telling this to their Congressional representatives.

CHAUNCEY D. LEAKE, M.D.

Sociology and Social Problems in Nursing Service — *By Gladys Sellew, Ph.D., R.N.* Philadelphia: Saunders, 1941. 344 pp. Price, \$2.75.

Adequate nursing care requires an understanding of the patient, his background, and his relationship to the society in which he lives. An appreciation of the effects of social and industrial conditions on health and the interrelationship of social and health problems as well as an understanding of the cooperative efforts which are contributing to their solution are a part of the professional preparation of the nurse. The presentation of the principles of sociology and their application to nursing is a large order for a single small book. In her attempt to cover a large field briefly, the author sometimes seems rather didactic, and she does not always emphasize the social factors and resources which might be of most importance to the average nurse. The young student might be somewhat overwhelmed by the problems which are presented and feel that a return to a primitive civilization is the only solution.

The units dealing with personality as a product of social life, the family, the community, and medical-social problems

will give the student a background for understanding the social and health aspects of nursing, and may stimulate her interest in public health nursing. This book will help the student to see nursing in relation to the community and society as well as to the individual patient.

The material is well organized, and the outline for the course in sociology in *A Curriculum Guide for Schools of Nursing* is carefully followed. Although this book was written as a text for undergraduate nurses, it could be read with profit by public health nurses who have had no basic courses in sociology. Each unit includes a bibliography which will guide the reader to references giving a more complete treatment of the problems. The glossy paper does not contribute to ease in reading.

ELLA E. McNEIL, R.N.

Sociology Applied to Nursing—
By Emory S. Bogardus, Ph.D., and Alice B. Brethorst, Ph.D., R.N. Philadelphia: Saunders, 1941. 294 pp. Price, \$2.50.

This book was written by a sociologist and a nurse as a text for the basic course in sociology for student nurses. The authors state that their aim is to develop a concrete treatment of sociological facts and principles and give a social setting for the profession of nursing. The material is organized according to the outline suggested in *A Curriculum Guide for Schools of Nursing*, and throughout the book application of psychological and sociological principles has been made to situations common to the nurse.

This book will give the young student nurse some understanding of the factors which affect personality development and of the special problems which the nurse meets in her professional activities. She should also gain some understanding of the organization and functions of the family and the community.

Many of the subjects are treated very superficially, and the instructor will need to provide supplementary readings and interpret much of the material to avoid misconceptions on the part of the inexperienced student. The discussion of the health department, the visiting nursing association, the Red Cross public health nursing service, and the school health service is inadequate and confusing. Some of the references might be questioned as guides to a student in the selection of the most authentic sources of information.

Because of the oversimplification of much of the material, this book would not serve as a very satisfactory reference for public health nurses.

ELLA E. McNEIL, R.N.

The Vitamin Content of Meat—
By H. A. Waisman and C. A. Elvehjem. Minneapolis: Burgess Publishing Company, 1941. 210 pp. Price, \$3.00.

This monograph will be a great convenience to investigators in the field of nutrition and to those engaged in such diverse fields as the vitamin assay of foods and the calculation of the vitamin content of human and animal dietaries. However, the scope of the book is too restricted and its presentation too technical to be of much value to the physician, the general reader, or the elementary student. On the other hand, it is an excellent monograph for advanced students of nutrition.

Data are given (mostly from the author's laboratory and hitherto unpublished) of the content in meat—raw and cooked—of the different members of the vitamin B complex—thiamin, riboflavin, nicotinic acid, pyridoxin, and pantothenic acid. The reputation of the authors is sufficient warrant for the reliability of these data.

There is a full discussion of the different assay methods of the members of the vitamin B complex, with comparative data on the results obtained by

different methods on the same material. This information is most timely and is badly needed.

Summaries are presented also of the vitamin A, D, E, K, and C content of meat. The data here were obtained from the literature.

A chapter is devoted to each of the vitamins of practical importance in human nutrition, giving the formulae and a brief discussion of the chemistry, pathology, and therapeutic uses. The discussion on therapy is uncritical and inadequate. To some extent this is compensated for by the large bibliography.

HENRY BORSOOK, M.D.

Annual Review of Physiology—
Vol. III.—By James Murry Luck and Victor E. Hall. Stanford University, Calif.: American Physiological Society and Annual Reviews, 1941.

This volume is the third in the series of annual reviews of physiology, which forms a companion series to the *Annual Reviews of Biochemistry*. The editors have attempted to obtain reviews which present a critical analysis of outstanding papers in which the relation of the new work to that of former years is indicated, and in many instances they have been successful to a high degree. The review by Feldberg on Histamine and Anaphylaxis is an excellent example, and among others might be mentioned the section on physiological problems

related to aviation in the review on Respiration, by Schmidt and Comroe, and the section on diet in relation to liver injury in the review on Liver and Bile by Hawkins. In such short accounts of the present status of important topics in Physiology the volume has its major value to workers in fields outside Physiology. The work is, however, of great value even when the author has limited himself to a critical résumé of the year's work in his field by presenting references and summaries in a readily available form.

HERBERT HOFF

One Hundred Years of Medicine in Minnesota—*Published by Minnesota State Medical Association, 1941.* 26 pp.

This publication by the Committee on Public Health Education of the Minnesota State Medical Association presents in pictorial form and with a minimum amount of text the story of a century of medical progress in Minnesota. The place of public health and of public health nursing is recognized with fair proportion and the reader can readily appreciate that high grade, modern medical care requires good facilities and is not a cheap commodity. This is a creditable production, comparing very favorably with similar efforts of other state medical societies.

R. M. ATWATER, M.D.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Definite, Positive, Clear—Its title tells you all you need to be told at this point about this excellent paper, which is commended to all.

BECKER, J. E. Nutrition in Pregnancy. *Am. J. Nurs.* 41, 11:1245 (Nov.), 1941.

"That One Talent Which Is Death to Hide"—Twenty-four statistical findings about the prevalence and causes of blindness come from the productive hopper of the National Health Survey. Of every hundred thousand, 83 were blind in both eyes, 326 in one. Diseases were the major cause of complete blindness, accidents of partial.

BRITTEN, R. H. Blindness, as Recorded in the National Health Survey—Amount, Causes, and Relation to Certain Factors. *Pub. Health Rep.* 56, 46:2191 (Nov. 14), 1941.

Ouch!—No specific dietary factor or metabolic condition has been proved to cause or control dental caries in the fully developed human tooth. This forthright conclusion ends a summary of the voluminous recent literature upon caries and metabolism. (There appears to be no reference to the papers on fluorine vs. dental caries, however.)

BUTLER, A. M. Metabolic Factors in the Cause and Control of Dental Caries. *New Eng. J. Med.* 225, 19:746 (Nov. 6), 1941.

Tough Food for (Administrators') Thought—Half a million men and women in the productive ages (20–64) are in institutions because of some serious physical handicap or incapacitating chronic disease. Sixteen million have the same troubles, but are at home.

Only some fifty-odd millions, presumed to be in health, remain and they must carry the load of all. The several diseases and impairments are listed in the order of frequency. This is only a part of the dreadful information that you should have.

HALLMAN, D. E. Health Status of Adults in the Productive Ages. *Pub. Health Rep.* 56, 43:2071 (Oct. 24), 1941.

Next Steps for the Blind—Opportunities and responsibilities of official and voluntary health agencies in the conservation of vision are pointed out in this story of what has been accomplished by some health services.

HEERING, R. E. Helping America by Saving Sight in Childhood through Health Services. *Sight-Saving Rev.* 11, 3:179 (Sept.), 1941.

Health for the Country Cousin—In certain rural parts of the Province of Manitoba, medical service is given through "municipal doctors" who are engaged by the community at an approximate family levy of \$4.50 per year. A survey of two years' experience in seven areas indicates that under the conditions prevailing the method is successful.

JACKSON, F. W. Morbidity Survey in the Municipal Doctor Areas in Manitoba. *Canad. Pub. Health J.* 32, 10:491 (Oct.), 1941.

Saving Children's Eyesight—Many more of us than the specialists in child hygiene will find this item a valuable bit of educational material. It is written in plain English for the laity but in the matter of ophthalmology,

who of us isn't in that category? Nine chances in ten, you too think that farsightedness is better than normal distance vision. It isn't.

KNIGHTON, W. S. *Children's Eyes*. Sight-Saving Rev. 11, 3:200 (Sept.), 1941.

One Small Straw That Points a Dreaded Wind—Before the war, deaths from tuberculosis in Glasgow were stabilized at 960 per annum. During the first two years of war the deaths increased by 200. And this increased mortality is maintained for 1941. The working ages suffered most, and this suggests the influence of overwork, strain, ill-spent leisure.

LAIDLAW, S., and MAC FARLANE, D. *The Causes Underlying the Recent Increased Incidence and Mortality from Tuberculosis in Glasgow*. Brit. M. J. No. 4212:436 (Sept. 27), 1941.

Icterohaemorrhagic Spirochetosis—An agglutination test is described which will demonstrate the presence of specific antibodies in Weil's disease of more than one week's duration. The pathologists probably know about this, and the rest of us won't be particularly interested, but the item impelled me irresistably to spell out the jaw-breaking heading.

PACKCHANIAN, A. *Positive Agglutination Tests in Suspected Cases of Weil's Disease*. Pub. Health Rep. 56, 45:2145 (Nov. 7), 1941.

Flies Found to Harbor Polio Virus—Large numbers of flies were collected about a summer (health?) camp in Connecticut in which poliomyelitis occurred and two carriers were detected. The flies were macerated in sterile water and the washings instilled or injected into monkeys. Typical experimental poliomyelitis was produced. A second specimen of flies was collected in Alabama near households where polio cases had occurred. Again it produced experimental poliomyelitis.

PAUL, J. R., *et al.* *The Detection of Poliomyelitis Virus in Flies*. Science. 94, 2443:395 (Oct. 24), 1941.

Preventing Congenital Syphilis—Pros and cons of the premarital and prenatal blood test laws are presented quite impartially. Though some impressive statistics of syphilis discovered through these measures are presented, the author finds it difficult to state his opinion upon the matter. In his conclusion he reports 10 per cent of fetal and neonatal deaths still due to syphilis.

PECKHAM, C. H., JR. *Legal and Therapeutic Aspects of Syphilis and Pregnancy*. J.A.M.A. 117, 22:1863 (Nov. 29), 1941.

That Ounce of Prevention—You'll agree with the observation in this paper that the ultimate solution of the problem of deficiency diseases lies not in their treatment but in their prevention through teaching and (more important) making it possible for the poor to secure the food they must have.

RUFFIN, J. M. *The Diagnosis and Treatment of Mild Vitamin Deficiencies*. J.A.M.A. 117, 18:1493 (Nov. 1), 1941.

Cultivating a Neglected Field—Postpartum care carried on for one year for 600 obstetric cases proved its value in preventing and treating sequelae of delivery. Child hygienists especially will be interested in the findings.

SEWALL, C. W., and MULLANEY, O. C. *Postpartum Care: Preliminary Report on Studies in a Follow-up Clinic*. New Eng. J. Med. 225, 20:777 (Nov. 13), 1941.

The Tuberculous After Three, Five, Ten Years—Thanks to annual physical examinations 62 per cent of the employees having tuberculosis were detected while in the minimal stage. Only 1.5 per cent of these minimal cases died, whereas a fifth of the moderately advanced cases and nearly half the far advanced cases died. Of the minimal cases that returned to work, three-quarters had been cured in a year

or less. Of the advanced cases, a third were cured after three years or more.

STEPHENS, M. G. Follow-up of 1,041 Tuberculous Patients. *Am. Rev. Tuberc.* 44, 4:451 (Oct.), 1941.

Mental Illness Can Be Prevented
—If you are one of those who enjoy an occasional sortie into some field of little immediate applicability to your present job, then I think you'll like this series of papers on the Delaware "Human Relations Classes" in which a classroom teacher leads the children to a clearer understanding of themselves and to better mental health.

TARUMIANZ, M. A. How the Human Relations Classes Were Started (and three related papers). *Understanding the Child* 10, 3:3 (Oct.), 1941.

Clamping Down on Hash Houses and Juke Joints—When 77,000 troops barge into a state for a month to carry out maneuvers, health problems multiply, as one may quite readily understand. What was done to minimize the worst health hazards is told all too briefly in this excellent report.

WILLIAMS, W. C., and MCGINNIS, G. F. *Pub. Health Rep.* 51, 43:2065 (Oct. 24), 1941.

Epidemiology Section

Philipp R. Rezek, M.D., Jackson Memorial Hospital, Miami, Fla., Pathologist

Unaffiliated

Neal E. Blanton, B.S., Cowlitz County Health Dept., Court House, Kelso, Wash., Sanitarian
Curtis R. Chaffin, M.D., M.P.H., 816 Oregon Bldg., Portland, Ore., Acting Director, Div. of Mental Hygiene, State Board of Health
Judson H. Clark, 627 W. Church St., Elmira, N. Y.

DECEASED MEMBERS

J. N. Baker, M.D., Montgomery, Ala. Elected Member 1930, Elected Fellow 1932, Health Officers Section

F. R. Dew, M.D., Oberlin, Ohio, Elected Member 1921, Elected Fellow 1923, Health Officers Section

R. Clifford Errickson, Long Branch, N. J., Elected Member 1937, Health Officers Section

Bernard Kohn, M.D., Philadelphia, Pa., Elected Member 1918, Elected Fellow 1923, Health Officers Section

Mrs. Frederick T. Lord, Boston, Mass., Elected Member 1912, unaffiliated

Charles Pecher, M.D., New York, N. Y., Elected Member 1938, Food and Nutrition Section

Roy C. Rehder, M.D., Mansfield, Ohio, Elected Member 1937, Health Officers Section

Ellen S. Stadtmuller, M.D., San Francisco, Calif., Elected Member 1929, Maternal and Child Health Section

WANTED: The following issues of the *American Journal of Public Health*—April, 1911; February, 1937; January, 1938; February, 1939; July, 1941; and August, 1941. The American Public Health Association will be glad to pay postage for the *Journals*.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearing house on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

UNASSEMBLED EXAMINATIONS IN WEST VIRGINIA

The Merit System Council of West Virginia, Box 873, Morgantown, has announced that it is expected that unassembled examinations will shortly be given for the following positions in the West Virginia State Health Department.

<i>Position</i>	<i>Salary per month</i>
Chief of Medical Services.....	\$325-\$400
Ophthalmologist	275- 350
Director of County Health Work.....	350- 400
Director, Maternal & Child Hygiene.....	350- 400
Director, Communicable Diseases	350- 400
Director, Vital Statistics	350- 400
Director, Industrial Hygiene.....	350- 400
Assistant Director, Maternal & Child Hygiene.....	320- 375
Assistant Director, Communicable Diseases (Venereal).....	320- 375
Assistant Director, Tuberculosis.....	320- 375
Venereal Disease Consultant.....	320- 375
Senior Health Officer.....	320- 375
Junior Health Officer.....	280- 320
Health Officer Trainee.....	\$200

Residence in West Virginia has been waived in consideration of the applications for these positions. However, residents of the state may be given preference in making appointments. Complete information may be obtained by writing to the Merit System Council.

VACANCY IN LOS ANGELES CITY HEALTH OFFICER POSITION

The City of Los Angeles is seeking qualified applicants for the position of City Health Officer paying a salary of \$7,200 per annum. While the city charter requires that candidates for this position be residents of the City of Los Angeles if possible, if insufficient competition for this examination is obtained, candidates who do not reside in the city may become eligible if they are otherwise qualified. From the experience of other agencies in this area it is probable that insufficient competition will be obtained and that it will be necessary to waive the residence requirements.

The City Health Officer is the Chief Administrative Officer of the City Health Department and plans and administers a broad public health program, including medical and inspectional services. He is responsible for the proper enforcement of health laws and ordinances and the prevention and control of communicable disease in the city.

Public health physicians who are interested in this position should communicate with the Los Angeles City Civil Service Commission, Room 11, City Hall, Los Angeles, California, for further information.

U. S. CIVIL SERVICE COMMISSION

The Commission has announced that applications will be received for positions as Senior Medical Officer (\$4,600), Medical Officer (\$3,800), and Associate Medical Officer (\$3,200) for appointments in the Public Health Service, with the Food and Drug Administration, Veterans' Administration, and the Indian Service. Forms for application may be obtained from the U. S. Civil Service Commission, Washington.

Junior Public Health Nurse. A civil service examination for Public Health Nurse (\$2,000) has been open for some time. Nurses who have been unable to qualify for this examination because of the experience requirement now have an opportunity to

qualify through a new Junior Public Health Nurse examination (\$1,800) which requires no experience. Applications are also being received for examinations now open for Junior Graduate Nurse (\$1,620) and Graduate Nurse for general staff duty (\$1,800). Further information and application forms may be obtained at any first or second class post office or from the Civil Service Commission, Washington.

POSITIONS AVAILABLE

Young woman, trained in Home Economics, for group contact work in behalf of an important commercial organization whose products are useful in the protection of public health and the National Nutrition Program. Experience in the public health field or related fields is essential. Office in New York, some travel involved. Write Box H, Employment Service, A.P.H.A.

Southern State Department of Health seeks physicians qualified by training and experience as County Health Officers or as Pediatricians. Write Box B, Employment Service, A.P.H.A.

Western State Department of Health will consider applications from physicians with experience and a degree in public health. Write Box S, Employment Service, A.P.H.A.

Physician with public health training to serve as full-time County Health Officer in rural South Atlantic area. Salary \$3,600 to \$4,000. Write Box C, Employment Service, A.P.H.A.

County Public Health Nurses for New Mexico. Must have four months' post-graduate instruction under one of the recognized public health nursing courses and one year's experience. Must drive and have a car. Address inquiry to State Health Department, Santa Fe, N. M.

Physician with either public health training or experience in local health department administration to serve as health director in a county health department in mid-western state. Salary \$4,000 and \$500 travel (flat rate). Well established department with offices in attractive little city of 10,000. Write Box T, Employment Service, A.P.H.A.

Laboratory Director—Bacteriologist—\$2,400. For combined hospital and health department laboratory with staff of 10 and visiting pathologist in charge of hospital aspects. Bacteriological experience and training especially desired. Opportunities for expanding program good. Reply Box G, A.P.H.A. Employment Service.

Wanted: Trained Public Health Nurse, starting salary \$1,500 per year and traveling expense, increase to \$1,700 within 6 months. Saginaw County Health Department, Saginaw, Mich.

The State Department of Social Security and Welfare, Crippled Children's

Division, of Phoenix, Ariz., has three vacancies to be filled. Examinations will soon be held for orthopedic nursing consultant, nurse-physical therapist, and medical social worker.

Further information may be obtained by writing to the Merit System Supervisor, Room 208, 128 North First Avenue, Phoenix, Arizona.

PHYSICIANS WANTED IN CINCINNATI

Carl A. Wilzbach, M.D., Commissioner of Health of Cincinnati, has announced that there are vacancies for white male physicians, aged 23 to 50, graduates of recognized colleges of medicine, licensed to practice in Ohio, for appointment to the Cincinnati Health Department. Duties include surveillance over communicable disease, infant and child welfare work, medical service for sick poor, epidemiological surveys of communicable disease, examinations for work certificates, school teachers, etc., vaccination, medical school inspection. Salary \$2,640 to \$3,360 plus transportation allowance of \$240 per annum. Eligible for a retirement system. Persons interested should communicate with Dr. Wilzbach, Commissioner of Health, City Hall, Cincinnati, Ohio.

PUBLIC HEALTH ENGINEER

Responsible professional public health engineering involving field investigations and office studies in the application of sanitary measures. The more difficult engineering and sanitation field surveys include supervision over public water supplies, sewerage systems and sewage treatment plants and review of plans for same, and promotion and supervision of sanitation programs. Minimum qualifications: Training and experience equivalent to 3 years' civil engineering experience, including 2 years in public health or sanitary engineering; or completion of an academic year of graduate study and a year's experience in sanitary or public health engineering; and graduation from a college of recognized standing with a major course in civil or sanitary engineering. The salary range is \$205 to \$250 per month depending upon experience. Apply Box E, Employment Service, A.P.H.A.

POSITIONS WANTED

ADMINISTRATIVE

Physician, M.D. Tulane, M.P.H. Johns Hopkins, age 31, experienced as health unit director, prefers administrative position in the South. A-488

Physician with M.P.H. from Johns Hopkins 1924, experienced as state director for communicable diseases, as county health officer and as director of field training center, will consider responsible position with good income. A-483

Dentist, University of Pittsburgh, D.D.S.; M.P.H. University of Pennsylvania 1941; experienced in practice, wishes an administrative position in public health, preferably at state level. M-450

HEALTH EDUCATION

Teacher and research worker, man, Ph.D., age 52. Extensive record as college professor of biology and hygiene and investigator, for the past two years engaged in research. H-499

Woman with M.S. in public health, University of Michigan, and Ph.D. in health education, New York University, experienced in public schools, teachers colleges, and community public health, now employed as health teaching supervisor, will consider position in school, organization, or industry. H-236

Young woman with Master's degree in Health Education, Teacher's College, Columbia University, and background of clinical laboratory work and biochemistry, seeks position as health educator in research or as laboratory assistant in public health. H-494

Health Educator, Negro, man with background of High School administration and M.S.P.H. from University of Michigan, seeks position in Health Education. Public agency or educational field. Excellent references. H-497

Woman, M.S. in public health, excellent graduate training in education, 8 years' experience as business executive (sales and publicity). Just completed year's research in community education. Seeks good administrative position. H-496

Health Educator, M.A. in Education, 10 years' background in community organization for public health education, also teaching of personal and community health at high school and college levels. Public health nurse, able to teach mental and social hygiene as well as general health education. East preferred. H-498

Health Educator. Man with M.S. in preventive medicine and public health. Negro. Seeks position in Health Education or field work with official or non-official agency. H-500

Health Educator, man 32, M.S.P.H. with excellent training and varied experience in education and public health. Would expect salary of \$3,000. Prefers national or state organization. Excellent references. H-405

Woman with master's degree in health education, 12 years' successful experience in public school and college teaching, administration and research. Will consider position in normal school, public schools, or in official or nonofficial health agencies. Prefers South or East. Available at once. H-501

LABORATORY

Milk Sanitarian and Technologist, age 37, Ph.D. Bacteriology, Wisconsin, 10 years' experience in milk and food sanitation from industrial and official angle, seeks administrative position with opportunity for research or investigational work preferred. L-381

Experienced Bacteriologist, man, 56, with long record as successful university teacher, research worker, and head of department of bacteriology and public health, desires new location in educational, research, or public health organization. Available at once. L-462

Chemist, Sc.D., Biochemistry, Johns Hopkins University. Age 31. Public health laboratory experience, teaching experience. Desires position with promise of advancement, preferably in commercial organization. L-461

Laboratory Director, unusually well qualified and experienced man, aged 41, Ph.D. with training at Michigan and Maryland. Excellent references. Will consider administrative, teaching or research position in public health. L-459

Experienced bacteriologist, young man of 33, Sc.B., who for several years has been in charge of state laboratory doing public health and diagnostic bacteriology, immunology and serology, will consider opening. L-427

SANITARY ENGINEERING

Engineer, age 38, 3 years' experience as district sanitary supervisor, state department of health, together with work on plumbing, heating and ventilation. Will consider position in the plumbing or heating field or state department of health. Prefers middle western or western states. E-453

Public Health Engineer, M.S. Harvard, experienced in public health and industrial hygiene, wishes position of better sort in public health engineering or industrial hygiene. E-470

Public Health Engineer, M.S. Harvard, with more than 10 years' experience including 5 years with state division of sanitation, is available. E-468

STATISTICAL

Public Health Statistician. Young man, M.S.P.H. Michigan, now employed as supervisor of state health project, experienced in medical research, epidemiology studies and vital statistics, seeks position in city or state health department in Midwest. S-458

Woman with academic, business and research experience in vital statistics, seeks a position in the vital statistics division of a state or city health department, preferably as registrar. S-459

Experienced and well trained public health nurse, with background of tuberculosis, venereal disease, school, industrial, and generalized services, will shortly be available for appointment. Three years as director of state nursing service. Experienced as university teacher of public health nursing. M.A., New York University. M-449

Opportunities Available

PUBLIC HEALTH PHYSICIANS—(a) Physician qualified to serve as chief of Bureau of Medical Service, state health department; \$400-\$440; East. (b) Epidemiologist for key appointment in eastern city; administrative experience in health department required; \$3,800-\$4,800. (c) Director, department of health and physical education; school system of midwestern metropolis, \$5,000-\$6,000. (d) Health commissioner; physician under 40 with considerable public health training required; full-time appointment; \$4,200. (e) Physician with background in public health desiring training in social hygiene; social hygiene division of municipal health department; unusual opportunity for training in epidemiological aspects venereal disease control, \$2,400-\$3,300. (f) Rural health officer; must be interested public health; but training unnecessary; \$225-\$300; South. (g) Young physician for public health appointment offering accredited training in public health obstetrics; minimum year's training obstetrics required; \$150, travel allowance. (h) City physician; southern community of 25,000; southerner preferred. PH1-1, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

STUDENT HEALTH PHYSICIANS — (a) Woman physician for immediate appointment to student health department, college for women; enrollment over 2,000; woman under 40 with teaching experience preferred; \$2,100, partial maintenance; nine-month term. (b) Young man particularly interested health education, qualified to assist in surgery, for student health appointment in exclusive small college; \$3,600; two out of three summers free. PH1-2, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

CHIEF SANITARIAN—Young man with college degree (preferably in engineering) and postgraduate training public health, plus three-five years' field experience required; appointment is with

district health department, midwestern county; \$2,400, travel allowance; headquarters in college town. PH1-3, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

BACTERIOLOGISTS — Appointments available with large pharmaceutical house for technicians trained in biochemistry and bacteriology, Master's degree or equivalent desirable, but not required. PH1-4, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

PUBLIC HEALTH NURSES—(a) Maternal and child health advisory nurse; duties include assisting supervising nurses in organized health units to develop their maternal and child health program; degree, certificate public health nursing, postgraduate training either obstetrics or pediatrics required; \$195, travel allowance. (b) Orthopedic field nurse; certificate public health nursing, postgraduate training orthopedics required; duties consist of giving direct service to crippled children in unorganized areas; \$165, liberal daily allowance while in field. (c) Staff nurse for state health department; public health nursing certificate required; \$135-\$160, travel allowance, mileage; West. (d) Public health nursing supervisor; minimum year's public health training, followed by two years' public health experience required; \$1,920, mileage. (e) Public health nurse; small New England community; public health nursing certificate required; \$1,800. (f) Student health nurse; duties include supervision of both out-patient and in-patient departments of student health service, eastern university; supervising experience required; \$1,300-\$1,400, maintenance, for school year. (g) Out-patient department supervisor; degree, background of experience essential; public health training desirable; must be qualified to reorganize and supervise out-patient department of university hospital; \$2,000, partial maintenance. PH1-5, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

Situations Wanted

PUBLIC HEALTH PHYSICIAN—B.S., M.D. degrees, state university; M.P.H., Johns Hopkins; four years, director of county health unit; recommended as highly skilled man in field of public health theory and administration. PH1-6, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

PUBLIC HEALTH NURSE—Graduate of fairly large training school; B.S. in nursing, University of Washington; certified public health nurse; eight years, city and county health work; two years, director of nurses, child welfare organization;

most recent appointment, consultant nurse in state department of health. PH1-7, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

BACTERIOLOGIST — A.B., M.A., midwestern university, bacteriology major; Ph.D., Yale, major immunology, minors public health, physiology; five years in charge of laboratory, large industrial company; no preference as to locality. PH1-8, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

NEWS FROM THE FIELD

THE NEW YORK ACADEMY OF MEDICINE ON "PLAIN WORDS ABOUT VENEREAL DISEASE"

THE Committee on Public Health Relations of the New York Academy of Medicine released the following statement on December 1:

The Committee . . . is seriously concerned with the information contained in *Plain Words about Venereal Disease*, by Dr. Thomas Parran and Dr. R. A. Vonderlehr that, despite the recent availability of better methods of treatment and prevention of gonorrhea and syphilis, the disease rates among the troops have been mounting during the year 1941. Irrespective of whether or not this claim is supported by the monthly venereal disease statistics for the current year which have not yet been released by the Surgeon General of the Army, the Committee on Public Health Relations is concerned that the controversy in Washington with regard to the propriety of publishing "Plain Words" may obscure the most important point at issue in this publication.

The reported attitude of some responsible military and civil officials in regard to the toleration and attempted regulation of commercialized prostitution in the vicinity of troop concentrations presents serious public health implications. Quite aside from the social and moral aspects of commercialized prostitution and the bribery, corruption and white slavery which it breeds, past experience has demonstrated that the medical examination of prostitutes is an untrustworthy method of venereal disease prevention and that organized prostitution, however regulated, is responsible for a large share of venereal disease among soldiers. One of the greatest triumphs of preventive medicine was accomplished by the celebrated General Order No. 77 issued by Pershing upon the advice of Dr. Hugh H. Young and Surgeon General Merritte W. Ireland to all commanders of troops in the AEF, which resulted in the lowest venereal disease rate ever recorded by any army up to that time. In view of this demonstration and the studies by Raymond Fosdick and Abraham Flexner, it is surprising that there are still any medical and lay advocates of the discredited method of so-called regulation of commercialized prostitution.

Commercialized prostitution is not officially approved or tolerated by responsible civil and military authorities in the State of New York, but we must nevertheless be concerned about the health and welfare of our young men in military service or in essential war industries in some other parts of the country.

In spite of the fact that communicable disease observes no state or local boundaries, there are still advocates for local option in the vicinity of military concentrations. Under the May Act passed by Congress in July 1941, the elimination of prostitution in the vicinity of military establishments is the law of the land. In this time of national peril, the protection of our military forces against the communicable diseases is of paramount importance.

The Committee on Public Health Relations of the New York Academy of Medicine wishes to record its opinion that commercialized prostitution still constitutes a most serious health hazard and that so-called regulation of prostitutes is thoroughly untrustworthy as a method of venereal disease control. The committee therefore endorses the major thesis of "Plain Words" by Drs. Parran and Vonderlehr and urges that the May law be invoked by the military authorities in localities adjacent to military concentrations whenever the U. S. Public Health Service and the new Division of Social Protection of the Federal Security Agency certify that they have been unable to persuade the responsible civil authorities to take effective action.

SUPPRESSION OF PROSTITUTION IN ARMY CAMPS

AMONG a number of resolutions which have grown out of the current controversy relating to the prevalence of venereal disease in the vicinity of army camps and with respect to the enforcement of regulations, especially the enforcement of the May Act by the Secretaries of War and of the Navy, are those from the Public Health Council of the State of New York and the Board of Managers of the New York State Charities Aid Association which are presented herewith.

Resolution passed by the Public

Health Council, New York State,
November 28, 1941:

WHEREAS, published reports indicate commercialized prostitution exists in the immediate vicinity of certain of the military establishments of the United States with alleged official reliance upon "regulation" of houses of prostitution, including the medical examination of prostitutes, as an aid in preventing the spread of venereal diseases, and

WHEREAS, this method has been proven many times in the past not only valueless but conducive to a false sense of security on the part of the public, thereby leading to increased exposure and increased venereal disease, and

WHEREAS, despite modern advances in diagnostic methods, a like result is as inevitable now as in the past, since a medical certificate of freedom from evidence of infection issued to a commercialized prostitute can apply only to the moment at which the examination was made, and can give no assurance whatever of freedom from infection immediately thereafter, and

WHEREAS, the State of New York has at considerable expense for several years conducted an intensive program for the prevention and reduction of venereal diseases, and with such apparent success that the rate of newly acquired syphilis has been reduced by more than half in the past four years, and the rate of rejections by Selective Service Boards on account of the venereal diseases has been much below that of the country as a whole and markedly below that of many of the states to which many residents of New York State have been sent for military training, and

WHEREAS, the Public Health Council has a proper concern for the health of the residents of the State who have been inducted into military service and is justifiably apprehensive lest the important gains of recent years be seriously jeopardized by the exposure of men in such service to venereal infections, and

WHEREAS, in the opinion of the Public Health Council, so-called "regulated" prostitution, including the medical examination of prostitutes, is as dangerous now as it has been in the past and will wherever practised lead to increased exposure and increased venereal infection, therefore be it

RESOLVED, that in view of the national interest involved, there should be a clearly stated policy established by the high command directing every local commander to take all proper means at his disposal to suppress commercialized prostitution in the

vicinity of military establishments and to cooperate actively with civil authorities in effectuating this objective rather than leaving the decision as to policy in this respect to the discretion of individual commanders, and be it further

RESOLVED, that the Secretary send a copy of this resolution to the President of the United States, the Secretary of War, the Secretary of the Navy, the Director of Defense Health and Welfare Services, the Chief of Staff of the Army, the Chief of Naval Operations, the Surgeons General of the Army, the Navy, and the Public Health Service, the Chairmen of the Committee on Military Affairs of the House of Representatives and of the Senate, and the Members of Congress from the State of New York.

Resolution adopted by the Board of Managers, State Charities Aid Association, December 12, 1941:

WHEREAS, during the first World War a law was enacted by which the Army and Navy Departments were given authority to eliminate prostitution in areas adjacent to military and naval camps and establishments, which law was carried into effect by the Army and Navy authorities with aid from local authorities, if available, with excellent effects as indicated by an unusually low infection rate of venereal diseases in the United States Army, and

WHEREAS, a similar bill introduced in Congress was approved and urged by this Board at its meeting in February, 1941, and subsequently became law, and

WHEREAS, it is currently reported that the Army authorities have not proceeded to enforce the May Act, and that the infection rate from venereal diseases in the present Army is very considerable, therefore
RESOLVED, that the Board of Managers of the State Charities Aid Association, on the recommendation of its Committee on Tuberculosis and Public Health, respectfully urges the authorities of the War and Navy Departments to make full use of the provisions of the May Act in all localities in which there is need therefor, and to indicate to all commanding officers of military and naval establishments that it is the settled policy of the Army and Navy that prostitution in areas near such establishments must be suppressed as a measure of protection of the health and efficiency of the American Army and Navy, and directing them to take all appropriate steps toward that result.

A MESSAGE FROM THE LATIN AMERICAN
DELEGATION AT THE 70TH ANNUAL
MEETING

SPEAKING for the Latin American Delegation at a luncheon meeting of the American Public Health Association in Atlantic City, N. J., October 17, 1941, Dr. J. C. Mussio-Fournier, the Minister of Public Health of Uruguay, expressed appreciation for the generous hospitality of the Pan American Sanitary Bureau and of its Director, Dr. Hugh S. Cumming. He expressed appreciation also to the American Public Health Association for having made possible the invitation to attend the 70th Annual Meeting and he congratulated the officers of the Association on the success of the meeting.

Continuing, Dr. Mussio-Fournier said:

The significance of this Congress is greater than that of a simple scientific meeting. America today is an oasis of peace in the midst of the most frightful storm through which humanity has passed. The same malignant forces which have trampled underfoot the rights and treasures which have been slowly accumulated in Europe is hovering as a terrible menace over the new world. Fortunately, America has reacted as one man in the face of the greatest danger which the continent has known since the Homeric days of her glorious independence.

Today at this important meeting there has been drawn up the first program for the sanitary and public health defense of the hemisphere. The Minister of Defense of Cuba, the Honorable Dr. Domingo F. Ramos, has contributed to our discussion a collaboration as complete as it is valuable.

America loves peace, but America loves liberty still more. The period of projects and discussions must end. The hour for resolution is at hand: rapid resolution, energetic resolution. All our moral and material forces must be rapidly blended into a single formidable defense. Only thus can we make of our America a fortress against which the fist of the aggressor may beat in vain. Our governments continue to maintain the diplomatic status of neutrality. But our peoples are fervent and enthusiastic adherents of the great English democracy which, with an epic resistance, perhaps heretofore unknown in the history of the world, is offering up even the last

drop of its blood to preserve the liberty of conscience, the most precious moral treasure which civilized man has enjoyed.

This precious treasure will be saved, thanks to the generous and formidable aid which this great democracy of the North is so disinterestedly lending to the cause of civilization, as the result of the energetic and outstanding resolution of its great President, Franklin Delano Roosevelt. You may be sure that if events require it, the descendants of those great patriots, Bolivar, San Martin, Artigas, Sucre, O'Higgins, Juarez y Marti, and their glorious brothers in the struggle for independence, will also offer their blood in the immortal cause of liberty.

SOUTHERN BRANCH A.P.H.A. MEETS
IN ST. LOUIS

A SUCCESSFUL meeting of the Southern Branch of the American Public Health Association was held in St. Louis, Mo., November 10-13, in the Municipal Auditorium. A program of general sessions and sessions of the Public Health Nursing Section and the Sanitation Section were well attended.

Organized in November, 1932, the Southern Branch has now held ten meetings, providing an opportunity for those in 17 southern states to share their public health experience and information. The Branch has met concurrently with the Southern Medical Association and its Public Health Section.

The Southern Branch has elected the following officers for the ensuing year:

President—P. E. Blackerby, M.D., Louisville, Ky.
First Vice-President—D. L. Cannon, M.D., Montgomery, Ala.
Second Vice-President—Mrs. Ruth George, Columbia, S. C.
Third Vice-President—L. M. Clarkson, Atlanta, Ga.
Secretary-Treasurer—R. H. Hutcheson, M.D., Nashville, Tenn.

The Engineers' Section of the Southern Branch has elected the following officers:

Chairman—C. H. Field
Vice-Chairman—R. E. Dorer
Secretary-Treasurer—J. L. Robertson, Jr.

At the meetings of the Governing Council of the Southern Branch it was reported that 16 states in the territory of the Southern Branch had appointed Membership and Attendance Committees to promote membership in the parent organization and in the Southern Branch. It was decided to redraft the Constitution and By-Laws to include all amendments and to provide that representation on the Governing Council from each of the southern states would be contingent upon each state paying the annual dues of \$10.

The Governing Council provided a plan under which it is hoped that the Secretary of the Southern Branch can attend the forthcoming meeting of the Western Branch, and an invitation was extended to the Secretary and other officers of the Western Branch to be in attendance at future meetings.

The Public Health Nursing Section of the Southern Branch presented a request that in future meetings provision be made so that the Nursing Section might meet at some time other than the first or last days of the meetings of the Southern Medical Association.

Selected papers from the scientific program of the Southern Branch are before the Editorial Board of the *American Journal of Public Health*, and it is expected that several will be carried in the pages of the *Journal* during coming months.

THE NATIONAL SCIENCE FUND OF THE NATIONAL ACADEMY OF SCIENCES

THE National Academy of Science, with offices in Washington, D. C., has announced the establishment in April, 1941, of the National Science Fund. The Academy will receive and the National Science Fund will apply large or small gifts for all physical and biological sciences. The Fund also offers its services as adviser to any prospective donor to science.

The National Academy of Science

was incorporated by Act of Congress, signed by Abraham Lincoln on March 3, 1863. The Academy is the official scientific adviser to the government and is in touch with scientific developments in the United States and other countries. It has an organization for reaching and consulting any special group of scientific investigators. Its membership now includes 324 leaders in all branches of physical and biological science, elected in recognition of highly distinguished achievements in scientific research.

In 1916 the Academy established the National Research Council primarily to coordinate the non-governmental scientific and technical resources of the country with the military and naval agencies in the interest of national security and preparedness. At the end of the war the Council was reorganized as a permanent organization for the promotion and maintenance of scientific research. Its membership is largely composed of appointed representatives of the major scientific and technical societies of the country and includes business men interested in engineering in industry.

With a view to setting up a single national center especially designed to advise donors to science and to assure them that their funds will be conserved and expended wisely and fruitfully, the National Science Fund has been created. Offices of the Fund are at 515 Madison Avenue, New York, N. Y. A brochure, *Philanthropy in Science*, can be obtained from the Fund on request.

NURSING SERVICES IN INDUSTRY

ON November 23, the Committee To Study the Duties of Nurses in Industry, from the Public Health Nursing Section, American Public Health Association, met in New York City to discuss the further conduct of the study which is being made in cooperation with the Division of Industrial Hygiene, National Institute of Health. Beside

the members of the committee, representatives from industrial nurses associations in Western Massachusetts, New York City, New Jersey, Connecticut, Indiana and Delaware attended the meeting.

Consideration was given to revisions of the form used for the preliminary study and the committee voted to enlarge its membership by inviting representatives from the American Nurses Association, and from the National League of Nursing Education. It is planned to establish a group composed of representatives from the American Association of Industrial Physicians and Surgeons, the American Industrial Hygiene Association, the American Medical Association Council on Industrial Health, the National Conference of Governmental Industrial Hygienists, and the National Association of Manufacturers' Committee on Healthful Working Conditions. It is expected that the study will get under way in January, 1942, and will require approximately one year to complete.

INDUSTRIAL HYGIENE STATE PROGRAMS

THE National Institute of Health has announced that with the completion of a new building to house its offices and laboratories by mid-January, the Arkansas State Board of Health is planning to begin an industrial hygiene program authorized by the state's occupational disease law adopted by referendum last November. The U. S. Public Health Service will lend the Board of Health a doctor, an engineer, and a chemist.

The Maryland State Department of Health under a law passed in 1939 has recently established a Division of Industrial Hygiene and allotted \$10,500 for industrial hygiene activities during the state's current fiscal year. It is expected that the state will employ a physician as director for the new division and the Division of Industrial

Hygiene of the National Institute of Health will lend an engineer and a chemist.

SURVEY OF MEDICAL SERVICES IN INDUSTRY

THE Division of Industrial Hygiene of the National Institute of Health, Bethesda, Md., has announced that the nation-wide survey of medical service facilities in industry which is being directed by W. J. McConnell, M.D., of the Metropolitan Life Insurance Company, in his capacity as Consultant to the U. S. Public Health Service is now in its preliminary stage. At present Dr. McConnell is surveying a number of industries in Pennsylvania to determine whether the proposed procedure and form for recording the data are adequate for the purposes of the survey.

NATIONAL DEFENSE IN INDUSTRIAL HYGIENE

IT has been reported that during the current year the research section of the Division of Industrial Hygiene of the National Institute of Health has a program of which 90 per cent pertains to national defense. More than 125 research projects have been undertaken and at present 91 are under way. These studies concern the toxicology of organic and inorganic substances, industrial pathology and bacteriology, analytical methods and services, problems of aviation medicine, and physics. Twenty-five additional problems have been outlined for investigation in the near future. Particular emphasis has been placed on studies of the toxicity of explosives, solvents, metals used in airplane and munitions manufacture, and components of synthetic rubbers and plastics.

SOUTHERN BRANCH, A.P.H.A., MEMORIALIZES DR. J. N. BAKER

THE following resolution was unanimously adopted by the Governing Council of the Southern Branch, Ameri-

can Public Health Association, at its 10th Annual Meeting in St. Louis, Mo.

WHEREAS, on the death of Dr. J. N. Baker on November 9, 1941, the South has lost one of its ablest physicians, one of its most distinguished state health officers, and one of its finest gentlemen, and

WHEREAS, Dr. Baker exemplified the highest order of Southern culture, sportsmanship, gentleness, consideration for others combined with constructive leadership in pioneering progressive public health procedures, therefore be it

RESOLVED, that the Southern Branch of the American Public Health Association record its profound sense of loss in the death of Dr. Baker, and be it further

RESOLVED, that a copy of these resolutions be sent to Mrs. J. N. Baker, the Secretary of the Alabama State Medical Association and the Secretary of the American Public Health Association, and be it further

RESOLVED that a copy of these resolutions be spread upon the Minutes of the Southern Branch of the American Public Health Association.

DOROTHY DEMING RESIGNS AS GENERAL DIRECTOR, N.O.P.H.N.

GRACE ROSS, R.N., of Detroit, President of the National Organization of Public Health Nursing, has announced that the resignation of Dorothy Deming, R.N., as General Director has been accepted effective January 1, 1942. Miss Deming had requested to be relieved in October, 1940, and again in March, 1941. In accepting her resignation the Board expressed its indebtedness to Miss Deming for her 14 years of devoted service, during several years of which she edited *Public Health Nursing*, later becoming General Director.

RUTH HOULTON APPOINTED GENERAL DIRECTOR N.O.P.H.N.

ANNOUNCEMENT has been made of the appointment of Ruth Houlton, R.N., as General Director of the National Organization of Public Health Nursing, effective January 1, 1942, on the resignation of Dorothy Deming, R.N. Miss Houlton has been with the

N.O.P.H.N. since 1935, coming from the Visiting Nurse Association in Minneapolis. She has been Associate Director of the N.O.P.H.N. for the last 6 years.

U. S. INDIAN SERVICE HOLDS REGIONAL MEDICAL MEETING

A DISTRICT medical meeting of the U. S. Indian Service for California, Nevada, and Utah, was held in November at Reno, Nev. Participating in a program which included national defense, tuberculosis management, the control of trachoma, problems in nutrition, health education, and other clinical subjects, were about 20 physicians of the Service under Dr. Ralph B. Snively, District Medical Director. Other speakers included Fred T. Foard, M.D., Surgeon U. S. Public Health Service, San Francisco; David Holladay, M.D., of the California Department of Public Health; O. C. Moulton, M.D., President of the Nevada Tuberculosis Association; Mrs. Christie A. Thompson, State Supervisory Nurse, Reno, Nev., and W. W. White, Sanitary Engineer of the Nevada State Health Department, Reno.

FAMILY-COMMUNITY PROJECT OF ADDISON, MICH.

THE Family-Community Project of Addison, Mich., has been announced for this rural community under the sponsorship of Albion College to begin January 1, 1942. An annual grant of \$10,000 has been made by the Kresge Foundation, and Dr. Regina Westcott Wieman, psychologist and social counsellor, has been appointed director. The project will be related to two courses in human relations and social technics in the Albion College curriculum.

President John L. Seaton of Albion College, referring to the tremendous stresses and strains on family relationships which the present period has

brought, has pointed out that the family is the social unit which can make for a more abundant American life. The Addison workshop, in combination with the courses in social technics conducted during the evenings, will be open to professional workers already engaged in health or community work.

AMERICAN RED CROSS ENROLLS MEDICAL TECHNOLOGISTS

AS of November 30, 1941, the American Red Cross in Washington announced that a total of 3,180 medical technologists of various sorts had been registered, of whom 286 were chemical laboratory technicians, 202 dental hygienists, 219 dieticians, 408 laboratory technicians and 219 x-ray technicians.

Enrollment is still open for persons in various grades.

A.P.H.A. ANNUAL MEETING BADGES

THE Army Medical Museum, Washington, D. C., would like to receive a collection of badges representing any past meeting of the American Public Health Association. At the request of Dr. Harry A. Davis, Major U.S.A. Retired, this request is given publicity in the thought that some member may wish to donate to the Museum a collection of these badges.

The Museum has recently added to its collection a medal commemorating the 50th Anniversary of the Association and the 100th birthday of Dr. Stephen Smith, founder, as well as a replica of the Sedgwick Memorial Medal.

ASSOCIATION OF SCHOOLS OF PUBLIC HEALTH

THE newly organized Association of Schools of Public Health held its first Annual Meeting in New York City December 20. Institutions holding membership in the Association are Columbia, Harvard, Johns Hopkins, Michigan, North Carolina, and Toronto. Lowell J. Reed, Ph.D., of Johns Hopkins, has

been President, Milton J. Rosenau, M.D., of North Carolina, Vice-President, and Henry F. Vaughan, Dr.P.H., of Michigan, Secretary.

SOCIAL HYGIENE DAY

THE American Social Hygiene Association announces that the Sixth National Social Hygiene Day will be observed on Wednesday, February 4, 1942. The theme is "Keep America Strong—Help Build Better Health."

The American Social Hygiene Association, 1790 Broadway, New York, N. Y., will provide advice and will suggest activities for coöperating groups.

PHYSICIANS NEEDED IN DEFENSE AREAS

DR. THOMAS PARRAN, Surgeon General of the U. S. Public Health Service, has announced that there is a need for physicians to practise in some defense areas. Physicians interested in securing further information should address Mr. George St. J. Perrott, National Institute of Health, Bethesda, Md.

STUDENTS OF PUBLIC HEALTH IN MICHIGAN

THE *News Letter* of the University of Michigan School of Public Health reports that at present there are 138 students pursuing the curriculum in public health at the University of Michigan. Nine of these students come from 7 foreign countries. The remaining 129 come from 30 states widely scattered. Michigan, Illinois, and Wisconsin have the highest representation—43 students are trainees.

ORAL HEALTH GROUP

THE Oral Health Group of the American Public Health Association has announced the election of Dr. C. R. Taylor of the Bureau of Public Health Dentistry, Michigan Department of Health, as its new *Secretary*, with Dr. A. O. Gruebel of Missouri as *Chairman*.

MICHIGAN PUBLIC HEALTH ASSOCIATION

AT its recent Annual Meeting, the Michigan Public Health Association elected the following new officers to serve until November, 1942:

President: William R. Davis, D.D.S., Lansing
President-elect: Emilie G. Sargent, R.N., Detroit

Vice-President: B. H. Warren, M.D., Grosse Pointe

Representative to A.P.H.A. Governing Council: William R. Davis, D.D.S.

Secretary-Treasurer: Marjorie Delavan, Lansing

The society announces that its 22nd Annual Meeting will be held in Grand Rapids, November 11-13, 1942.

IDAHO PUBLIC HEALTH ASSOCIATION

THE following new officers were elected by the Idaho Public Health Association at its second Annual Meeting held in October:

President: Dean John R. Nichols, Pocatello
First Vice-President: H. H. Rhodes, Coeur d'Alene

Second Vice-President: Mrs. R. L. Brainard, Wardner

Third Vice-President: Mrs. Otto Leuschel, Lewiston

Fourth Vice-President: Mrs. Emma Clouche, Twin Falls

Fifth Vice-President: A. H. Christiansen, Boise
Secretary: H. C. Clare, Boise

Treasurer: Lucy M. Higgins, Boise

L. J. Peterson was continued as the society's representative to the Governing Council of the A.P.H.A. and Fred T. Foard, M.D., of San Francisco was elected the first Honorary Member of the Idaho Public Health Association.

ILLINOIS PUBLIC HEALTH ASSOCIATION

THE Illinois Public Health Association at its Annual Meeting held on December 4, 1941, elected the following officers for the coming year.

President: H. F. Babbitt, M.S.
Vice-President: W. D. Dotterrer, B.S.
Secretary-Treasurer: H. A. Orvis, M.D.

Council members holding over until December 1942:

Alice Miller, C.P.H.
 J. H. Beard, M.D.
 E. A. Piszczek, M.D.

Council member elected for one year:
 Melvin H. Dobbs, B.S.

Council members elected for two years:

Mabel McClanahan, R.N.
 E. K. Musson, M.D.
 H. J. Shaughnessey, Ph.D.
 W. W. Talbert, M.D.

TEXAS PUBLIC HEALTH ASSOCIATION

AT its 19th Annual Meeting held in Corpus Christi in November the Texas Public Health Association elected the following officers to serve for the ensuing year:

President: Burke C. Brewster, M.D., Fort Worth

President-elect: Horace E. Duncan, M.D., Dallas

First Vice-President: Harold A. Wood, M.D., Austin

Second Vice-President: Katherine King Baker, R.N., San Antonio

Executive Secretary: Alan C. Love, Austin

The 1942 Annual Meeting of this Society will be held in Austin in the fall.

THE AMERICAN SOCIETY OF TROPICAL MEDICINE

THE American Society of Tropical Medicine held its 37th Annual Meeting in St. Louis, November 10 to 13. The officers elected were as follows:

President: Dr. Ernest Carroll Faust, New Orleans, La.

President-elect: Dr. N. Paul Hudson, Columbus, Ohio

Vice-President: Dr. Joseph S. D'Antoni, New Orleans, La.

Editor: Col. Charles F. Craig, San Antonio, Tex.

Secretary-Treasurer: Dr. E. Harold Hinman, Wilson Dam, Ala.

Councilors: Dr. Andrew J. Warren, New York, N. Y., Col. James S. Simmons, Washington, D. C.

Member of Editorial Board: Dr. Justin Andrews, Atlanta, Ga.

During the meetings the Bailey K. Ashford Award in Tropical Medicine was presented to Dr. Lloyd E. Rozeboom of the Johns Hopkins School of Hygiene and Public Health, Baltimore.

HARBEN LECTURES

THE Harben Lectures of the Royal Institute of Public Health and Hygiene were given this year at the University of Toronto, December 1, 2, and 3, by Elmer V. McCollum, Ph.D., Professor of Biochemistry at the School of Hygiene and Public Health, Johns Hopkins University, Baltimore. The subject was "Nutritional Science and Public Health."

DELAWARE PUBLIC HEALTH ASSOCIATION ORGANIZED

AT a meeting in Wilmington, Del., on November 28, the Delaware Public Health Association was organized and the following officers elected:

President—Edwin Cameron, M.D., M.P.H.
First Vice-President—G. H. Gehrman, M.D.
Second Vice-President—Mrs. Anna Van W. Castle, R.N.
Secretary—G. Taggart Evans
Treasurer—Roger Murray, M.D.

Steps are being taken to apply for affiliation of the Delaware Public Health Association with the American Public Health Association.

AMERICAN ACADEMY OF TROPICAL MEDICINE

AT its meeting on November 12 in St. Louis, the Theobald Smith Gold Medal of George Washington University was awarded to Admiral E. R. Stitt, M.C., U.S.N., retired. The following officers were elected for the year 1942:

President—Dr. H. C. Clark
Vice-President—Dr. L. W. Hackett
Treasurer—Dr. T. T. Mackie
Secretary—Dr. E. C. Faust
Councilor—Dr. A. C. Chandler

AMERICA'S TOWN MEETING OF THE AIR announces a \$1,000 prize essay contest on the subject "What Must We Do to Improve the Health and Well-being of the American People?" Two sets of identical prizes are offered for adults and youths. Persons 21 years of age and over are privileged to compete in the Adult Division, and persons under 21 years of age in the Youth Division. The first prize in each division is \$250 in cash plus a free trip to New York to appear on "America's Town Meeting of the Air"; the second prize \$100 in cash; the third prize \$50; and there are 10 prizes of \$10 each for honorable mention.

Essays are not to exceed 1,000 words in length. Envelopes containing essays must be postmarked not later than February 1, 1942. Contestants are requested to indicate on their essays whether they are entered in the Adult or Youth Divisions.

Essays should be addressed to:

Essay Contest Editor
 Town Hall
 123 West 43rd Street
 New York, N. Y.

MC GILL OFFERS DIPLOMA IN VETERINARY PUBLIC HEALTH

DR. GRANT FLEMING, Chairman of the Department of Public Health and Preventive Medicine at McGill University, Montreal, has announced the organization of a post-graduate course for veterinarians at McGill University in the Department of Public Health and Preventive Medicine of the Faculty of Medicine, leading to a Diploma in Veterinary Public Health (D.V.P.H.) to prepare veterinarians for the public health services and for employment with commercial firms engaged in animal industry. The first class enrolled for the session 1940-1941.

As in the case of all undergraduate students in the professions, the undergraduate training for the veterinarian

aims to prepare him for general practice. Through this graduate course he is prepared to undertake public health work in accordance with the present demands of the public health program where the veterinarian has been brought into the organization to assume responsibilities in connection with food inspection, particularly with the control of milk supplies.

AMERICAN STANDARDS ASSOCIATION

THE American Standards Association has announced the completion and approval of the American Defense Emergency Standard Allowable Concentration of Cadmium-Z37.5-1941. The standard as at present formulated will be in effect only during the period of the emergency, after which it will be reviewed by the Sectional Committee.

SOCIAL SERVICE AND DEFENSE

"MOST welfare officials will feel a strong and almost overwhelming desire to be a part of a bombing crew headed for Japan. We would want to do it even if we knew it was to be a one way flight. But let's be sensible. We know that most of us wouldn't make third rate mechanics. There is a job that we do know. It's a job which is vital to defense. It's a job essential to the maintenance of morale."

"Eric Biddle speaking before the Senate Finance Committee quoted a high British official as saying that *the greatly expanded social services in England did as much to win the Battle of Britain as the RAF*. If this is true, our job is one of major importance. Most people fear loss of security even more than they fear death by bombing. They are very sensible to feel this way because British experience indicates that modern war threatens their homes more than it does their lives. The English people know that no matter what happens to their homes as a result of air raids they don't have to worry about

their economic security. Their universal insurance will pay for and enable them to rebuild—some day. Through the social services their families will be fed, clothed, given shelter and medical care. What is lost is lost by all. What is saved is for the use of all. On such a foundation morale is built."—*Washington News Letter on Social Legislation*.

MARYLAND ADOPTS REGULATIONS FOR CONTROL OF COMMUNICABLE DISEASES

DR. RILEY recommended that regulations for the control of communicable diseases, as prepared by the American Public Health Association, be used and adopted by the State Board of Health. After discussion, on motion of Dr. Williams duly seconded and carried, it was ordered that the Report of the Subcommittee on Communicable Disease Control of the Committee on Research and Standards of the American Public Health Association, 1940 revision, as adopted by the United States Public Health Service (in their *Reprint 1697*), entitled *The Control of Communicable Diseases*, be adopted by the State Board of Health as a guide for policy determination in the matter of controlling communicable diseases in the State of Maryland.—*Excerpt from Minutes of Meeting of State Board of Health held on November 27, 1941*.

Number 2

Health Department Service in War Emergency*

M. F. HARALSON, M.D.

Territorial Commissioner of Public Health, Honolulu, T. H.

FOR the past year there has been a gradual and continued increase in the duties and responsibilities of the Territorial Health Department, particularly on the island of Oahu. During this period, primarily as the result of the national defense program, there was a rapid increase in the population on the island, requiring additional public health services, especially in environmental sanitation, communicable disease control, food inspection, restaurant sanitation, public health nursing, supervision of water supplies, and problems relating to housing. A situation taxing the department beyond the point of efficiency existed and had been a cause for concern, even before the President, on May 27, declared a state of national emergency.

The Territorial legislature meeting in special session in October, 1941, recognized the acute needs of the health department and provided five additional sanitary inspectors as well as additional funds for the Tuberculosis Bureau of the health department.

Immediately following the President's declaration, the various departments of the federal government, already interested in military and civilian health and becoming more concerned for increased protection and conservation of the national health resources, urged expansion of public health services upon state and territorial health departments.

Because of Hawaii's distance from the mainland and the possible disruption of shipping, its military and naval importance and its strategic location, the health department recognized not only the need for expanding its regular functions but also the necessity for preparing for any type of emergency. Plans for improving the organization were formulated. Bureau chiefs were instructed to order and keep on hand sufficient supplies for the effective operation of their respective divisions for a period of at least 6 months. Biologic supplies, certain drugs necessary for emergency use, and laboratory supplies and equipment were recognized as especially important items. Measures for the protection of water supplies and sewage disposal systems in the event of damage, espe-

cially on Oahu, were carefully considered. Plans were evolved to provide a satisfactory sanitary inspection service under emergency situations. A course in first aid instruction was organized for the public health nursing force. It was anticipated that the nurses would be called upon for additional services during an emergency, including first aid work, bedside nursing care, and obstetrical and delivery service. Plans were made for gearing up all public health services to meet the impending war emergency.

When the Honolulu Disaster Council was organized, the Territorial Commissioner of Public Health was named chairman of a health and sanitation committee, composed of representatives of various related health, medical and welfare agencies. It was pointed out in the preliminary report by the committee that its functions would be practically identical with those normally carried on by the Board of Health, except for necessary expansion in specific activities to meet emergencies as they developed. It was recognized, in the event of war, that the problem would not be so much revising the type of service offered by the health department but extending its normal program and correlated services with those of the civil and military authorities and other agencies concerned with the promotion and conservation of health.

Seven months after President Roosevelt's declaration, Pearl Harbor was attacked by an enemy force. The first bombs were dropped on the island of Oahu just before eight o'clock, Sunday morning, December 7, and later that day martial law was established. The military governor asked that all departments of the Territorial Government continue their special functions.

Within an hour after the first bombs fell, the executive heads of the health department were in conference and plans and arrangements were made for

carrying out the various services which seemed to be required at the moment. An inventory was taken of the biologic supplies on hand at the health department and the various pharmaceutical supply houses in the city. All members of the health department on Oahu were placed immediately on 24 hour call. Day and night service was established at the office of the Board of Health and was maintained for a period of two weeks following the initial attack.

A close liaison was established with the medical departments of the Army and Navy, the medical director of the first aid stations, the medical officer in charge of the Emergency Hospital, and municipal authorities, particularly those in charge of the water supplies, the sewerage system and garbage collection. All were urged to utilize the facilities of the health department to the greatest possible extent.

In order that appropriate measures for the prevention and control of communicable diseases might be instituted at the earliest possible moment, instructions were sent immediately to all physicians requesting the reporting of communicable diseases by telephone. Physicians were also requested to report all cases of illness suspected of being caused by contaminated food, milk, or water. This communication was followed by an order from the office of the military governor, directing physicians to comply with the request. A number of cases of acute gastroenteritis were reported. Epidemiological investigations and laboratory analyses were made. Most of the cases were traced to consumption of food which had been kept too long under improper refrigeration. No unusual prevalence of communicable diseases occurred.

After the attack, requests by hospitals and physicians in charge of first aid units were made for various essential biologic supplies. Prophylactic tetanus antitoxin was in particular demand. Re-

quests were excessive in some instances and physicians were advised to limit their requests to those immediately needed.

An immunization station for inoculation against typhoid fever and vaccination against smallpox was opened in the office of the Board of Health. Restaurant and general sanitary inspection services were intensified. Food supplies were carefully checked. Dairy inspection service was augmented and every assistance given to insure a continued supply of clean and wholesome milk and dairy products.

During the first few days rumors were current that the water supply had been contaminated or poisoned, none of which, upon investigation and examination, were found to be true. Water samples were immediately collected at various points throughout the city by Board of Health inspectors working in close coöperation with the Board of Water Supply. Bacteriological, chemical, and physical analyses were made. A portable chlorinator and a supply of chlorine gas purchased for emergency use were available, but thus far have not been required. Fortunately, no damage to water or sewerage systems in civilian districts was sustained during the first attack, which was limited for the most part to military objectives.

In view of the close proximity of residential districts to many military objectives, it became immediately necessary to evacuate a large number of civilians and military dependents to sections of the island removed from the points of attack. One of the important services rendered by the nursing department was the health supervision at evacuee centers where large numbers were being housed in schools, churches, and other community buildings. A number of nurses reported to first aid stations and hospitals for emergency nursing services. Other nurses, particularly in rural districts, supervised the setting up of first

aid stations and the obtaining of necessary supplies for their operation.

In order to make available additional beds in local hospitals for war casualties, it was necessary to evacuate certain patients for home care. Public health nurses were placed on call for bedside nursing care of these and other patients upon the request of a physician. Private physicians were notified that this service was available and were urged to utilize public health nurses when private nurses were not obtainable.

In anticipation of possible difficulties of transportation and the need of hospital space for other purposes, the Bureau of Maternal and Child Health developed a plan to assist in the delivery of prospective mothers in their homes. Delivery packs were prepared by the nursing division and made available for use. Obstetrical services were rendered by the public health nursing force in a small number of instances.

The general clinic program of the Bureau of Tuberculosis was somewhat curtailed. However, a number of sputum negative cases were discharged from the tuberculosis sanatorium on Oahu, and placed under the supervision of the outpatient clinics and public health nurses.

The Bureau of Mental Hygiene reported that a number of individual cases had come to their attention who had been on civilian defense duty too long without rest. These cases were given general treatment. Other mental patients who had become adjusted and discharged returned for treatment.

The Bureau of Pure Food and Drugs made chemical analyses on water and food when contamination or chemical poisoning was suspected.

Other administrative details requiring immediate attention were proper identification of all employees, including registration and finger printing, rationing gasoline for all cars used on official business, requisitioning gas masks, and

adjusting duties of personnel to care for vacancies caused by the induction of employees into the armed forces.

Although the first attacks were directed solely on the island of Oahu, it is needless to say that the suspense on the outside islands was as great if not greater than on the island of Oahu. With the radio and other methods of communication suspended shortly after the engagement began, followed only by occasional brief instructions to the public, the outlying islands were isolated. It was impossible for the health department to obtain any information or to issue instructions to the outlying districts. It is noteworthy, however, that the health department's representatives on each of the outer islands, coöperating with the Army and other officials, immediately took steps to protect the water and food supplies, strengthen the control of certain communicable diseases, and to utilize other public health services to the best advantage to meet local conditions. Extra biologic supplies and drugs were distributed to the several islands as soon as transportation became available.

The Territory of Hawaii will continue to play an extremely important part in the prosecution of the present war. What new health hazards may arise cannot at present be foreseen. Although many health problems will be aggravated because of the war, others may become less acute. Certain general principles of public health and valuable experience already gained will guide health officials in this emergency.

The Board of Health will continue to coöperate closely with the military authorities and other governmental and private agencies in the protection of the public health. Every effort will be made to maintain and safeguard water supplies, milk, and other vital foods. Regulations for the control of communicable diseases will be strictly enforced, lest abnormal conditions lead to the outbreak of an epidemic. Because of the important bearing of community health on morale, the health department through its various services will attempt to teach the public to make an intelligent adjustment to the current war emergency.

Stamp Out Gonorrhea Now!

JOHN L. RICE, M.D., F.A.P.H.A.

Commissioner of Health, City of New York, President, American Public Health Association

GONORRHEA, next to the common cold, is estimated to be the most prevalent communicable disease. It is the cause of great disability among the armed forces as well as among industrial workers. If health departments and other public health agencies support a well conceived and expertly conducted anti-gonorrhea campaign with the enthusiasm and determination that they brought to typhoid fever prevention, they can and should get comparable returns in the decrease of illness, increase in the number of man-hours available for production, and lives saved.

Never until now has the public health officer been equipped to deal effectively with gonorrhea. Until the chemotherapeutic attack by the sulfonamides, he had no specific therapy for this disease. Gonorrhea, dependent for its cure on the dexterity of the physician, has indeed been the "stepchild" of medicine. Past campaigns against the venereal diseases have of necessity been aimed almost exclusively at syphilis.¹ Against gonorrhea the health officer was armed with little more than a pious wish. Manual attack upon a virulent gonococcus in the urethra or in the cervix was often meddlesome therapy and oral therapy was much the same as that at the beginning of the 19th century.

Until recently the organization of a gonorrhea clinic necessitated expensive equipment, costly instruments, and a highly trained staff to carry out the delicate procedures deemed necessary. Specific chemotherapy has, in the great majority of cases, rendered obsolete all

previous types of therapy. Sulfathiazole makes it possible for any practitioner or health officer, however remote from the laboratory, to control gonorrheal infections. It is possible that other more efficient sulfonamide drugs may be developed in the near future. One of these, sulfadiazine, is already in use, but has not been so thoroughly studied, nor is it so generally available, as sulfathiazole.

Dr. Edward L. Keyes, writing from the viewpoint of the urologist, has said: "The prime essential in the successful treatment of gonorrhea is to get the physician out of the urethra. If chemotherapy has done no more than this, our patients would have much to be thankful for."²

But it has done far more than this. In sulfathiazole the physician and health officer have an almost ideal remedy wherewith to attack gonorrhea. Its forebear, sulfanilamide, when used for treating gonorrhea, produces in some instances toxic disturbances. Yet Dr. R. A. Vonderlehr, Assistant Surgeon General of the U. S. Public Health Service, tells us that "only 200,000 tablets of this compound [sulfathiazole] were reported purchased and distributed by state health departments during the first half of the present [1941] fiscal year, as compared with three and one-quarter million sulfanilamide tablets."³

Health departments and public health workers must make use of the most efficient compound now available if they wish to stamp out gonorrhea. State, county, and city health departments will recognize that here is an oppor-

tunity they must press to the utmost. The war emergency presents an additional reason.

Sulfathiazole in appropriate dosage, 0.5 gm., four times daily (serious injury may result if given in larger dosage) usually excites no toxic reaction and almost never causes the grave reactions with which sulfanilamide has made us familiar. Sulfathiazole after about ten days of treatment cures 85 to 90 per cent of gonorrhea cases, acute or chronic, regardless of age, sex, or race. The remainder of the uncured patients usually respond favorably to further treatment with the same medication.⁴

An effective public health policy for the attack on gonorrhea is now for the first time practicable. We now have the power to stamp out gonorrhea. Enteric fever has been conquered with less.

The "Stamp Out Gonorrhea Now" campaign should emphasize, first, that the disease can be cured simply, effectively, and in a short time, and, secondly (and of no less importance), that sources of infection and contacts can and must be followed up. Events of the past decade have developed in our people a new social conscience.

Proper, adequate, well publicized facilities should be provided in every community for the diagnosis and treatment of gonococcal infections for those unable to pay a private doctor. Those who can afford to pay should be urged

to seek the service of a private physician. Health departments should assume leadership in providing the physicians of each community with up-to-date information on the modern diagnosis and treatment of gonorrheal infections.

Public health agencies should not only recognize their new responsibilities in this field but should take immediate action to carry out their obligations. A well planned anti-gonorrhea campaign, similar to that against syphilis, is applicable today and with prospects of even more immediate and impressive results.

Uniformity in Control of Communicable Diseases*

HAVEN EMERSON, M.D., F.A.P.H.A.

Professor of Public Health Emeritus in Residence, De Lamar Institute of Public Health, College of Physicians and Surgeons, Columbia University, New York, N. Y.

AT the forty-third annual meeting of the American Public Health Association and the fifteenth annual conference of sanitary officers of the State of New York at Rochester, N. Y., a symposium on the administrative control of infectious diseases was held on September 10, 1915, under the joint auspices of the Section of Public Health Officials and the Department of Health of New York City.

The impetus for such a conference on the oldest, best developed, most widely recognized and generally effective of the functions of civil health authority was an inquiry in person and by mail correspondence between the director of the Bureau of Preventable Diseases of the Department of Health of New York City and the late Dr. John S. Billings and officers of health of a considerable number if not all of the cities of 100,000 population and over in the United States.

This exchange of information as to the prevailing administrative policies and regulations intended for the control of the common acute communicable diseases revealed striking and inconsistent variations in such matters as notification, verification of diagnosis, placarding of premises, isolation and quarantine periods, terminal fumigation, disposal of

the dead, and supervision of carriers. An effort seemed to be called for to determine an optimum or adequate procedure which would at the same time be consistent with the facts established by the medical sciences, be acceptable to prevailing medical opinion, and be practicable of enforcement by educational persuasion or the authority of sanitary codes.

Ten papers were presented, six by officers of the Department of Health of New York City: Drs. John S. Billings, William H. Park (two), S. Josephine Baker, Robert J. Wilson and B. F. Knause, the other four by Drs. F. G. Curtis, Health Officer of West Newton, Mass.; A. J. Chesley of Minnesota State Department of Health then as now; C. S. Caverly, the State Health Officer of Vermont; and C. J. Hastings, the Health Officer of Toronto, Canada.

As a result of the evidence and opinions expressed in the papers and discussion that followed a committee of the Section on Public Health Administration was appointed in October, 1916, to formulate Minimum Requirements for the Control of the Common Communicable Diseases. The first report of this committee was published in *Public Health Reports*, October 12, 1917, Vol. 32, No. 41. The report as published was presented to the Section on Public Health Administration on October 19, 1917, at the forty-fifth annual meeting of the Association in Washington. A

* Read before the Health Officers Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 16, 1941.

note in the program announced that "at least one hour will be given to discussion of the report."

At that time the nations within the scope of the A.P.H.A. were pressing every resource of materials and intelligence into the service of their armed forces. Nothing but the most effective and wise measures for health protection of the civilian population as for the Army and Navy was to be thought of. The discussion was active and vigorous, not to say violent, as one after another of the traditional but unsupported common procedures was attacked and discarded by the committee. No essential changes were made in the report, which was approved by the Section and endorsed by the A.P.H.A. and the U. S. Public Health Service, and was made official for use by the Army Medical Corps in this country and in the A.E.F.

The report did not do precisely what the committee was asked for. Instead of formulating minimum requirements for the control of the common communicable diseases, the committee presented a brief synopsis of the established facts concerning each notifiable communicable disease, acceptance of which would determine the procedures, rules, and regulations likely to prove useful in prevention or control of the respective diseases. The report put into the hands of the health board, council, or officer the facts upon which sanitary ordinances dealing with control of communicable diseases could be based, leaving it to local or state jurisdictions to phrase their regulations in ways consistent with the statutes or charter provisions of the various states and cities.

On October 11, 1926, at a joint session of the Section on Public Health Administration and the Committee on Administrative Practice at the fifty-fifth annual meeting of the A.P.H.A. and the twenty-fifth annual conference of New York State Health Officers at Buffalo, N. Y., the second report of the Com-

mittee on Communicable Disease Control was presented and discussed at length. Such changes as were warranted by additions to our knowledge of the natural history of the notifiable communicable diseases during the intervening ten years were incorporated in this report, which was again approved by the Section, by the Association and by the U. S. Public Health Service. This report was published in *Public Health Reports*, December 17, 1926, Vol. 41, No. 51.

The third report of the committee, now under the auspices of the Association Committee on Research and Standards, with still further changes to bring it up to date with the growing accuracy and completeness of medical and epidemiological information, was published in *Public Health Reports*, August 9, 1935, Vol. 50, No. 32, as approved by the A.P.H.A. and the U. S. Public Health Service.

At the time of the 1940 meeting of the Association in Detroit, October, 1940, a request was made by the Surgeons General of the Army, Navy, and Public Health Service, and by the American Medical Association for an immediate revision of the report to meet the medical needs of the defense effort of the nation. The committee's fourth report prepared in October, 1940, was published as *Reprint No. 1697* from the *Public Health Reports* in January, 1941, is now the official text of the A.P.H.A., and is in use by our armed forces and by the U. S. Public Health Service.

You will I trust pardon the detail with which I have related the history of this effort on the part of our Association to make convenient and widely available the basic facts which must in any event determine the formal official administrative control of the notifiable communicable diseases, in view of the further information I now present.

In 1939 on behalf of the Committee on Administrative Practice I studied the

procedures for communicable disease control in effect in 56 political units of the United States by correspondence with officers of state, insular, and territorial health jurisdictions, to learn the extent of their variance from or agreement with those approved by the Association and the U. S. Public Health Service. Shortly thereafter I made a similar study of the procedures in effect in the 9 provincial health jurisdictions of the Dominion of Canada. The results of these two studies were presented before the Conference of State and Provincial Health Authorities of North America on April 22, 1939, and the joint session of the Canadian Public Health Association and the Ontario Health Officers Association on June 12, 1939, respectively, and these were published in the July, 1939, issues of the *American Journal of Public Health* and *Canadian Public Health Journal* respectively. Let me quote two short paragraphs from these communications.

The inconsistencies between reasonably exact experience or observation of incubation and communicable periods of these notifiable diseases and much of the regulation of isolation and quarantine as implied or specified in the publications of state health authorities, and in the main obligatory upon the respective subordinate health jurisdictions of the states, appear to me to be so considerable in number and degree as to justify your attention.

.

You will find more numerous, and often quite inexplicable inconsistencies between fact and application in the requirements of the states of the United States, than among the provinces of Canada, but it would appear that even in the latter there are expressions of legal authority too varied to carry conviction of their reasonableness or necessity in all instances.

In recent months I have again made inquiries as to the extent to which regulations are consistent with established fact to meet the request of your Section Secretary that I present this subject for your consideration. It would appear

that there remain, or have been incorporated in the sanitary regulations and public health laws of a considerable number of our states, requirements that contribute little if at all to the control of the communicable diseases in question, because they are based upon misinformation as to the natural history of the disease in question. Furthermore there are frequent instances of differences of health procedures within states, in cities, and other local jurisdictions which reveal a confusion in the minds of the respective health officers which can hardly have a favorable effect upon physicians and patients in these communities.

About 15 of the states and several of the insular and territorial health jurisdictions operate under health laws and ordinances which include effective rules and regulations for communicable disease control which are practically identical or consistent with the procedures described in the current report of the committee. In most if not all of the other state, insular, and territorial health jurisdictions there are departures more or less marked from those which present-day knowledge of the communicable diseases would suggest as reasonable and sufficient.

Without attempting the tedious and perhaps invidious process of criticism of particular states, it can be said now as at any time over the past twenty-five years that one or more of the following types of unsuitability characterize the control measures required for one or more of the communicable diseases in about two-thirds of the states: lack of notification of some disease for which modern standards of health service appear to demand notification; placarding premises where cases of various communicable diseases are reported, under circumstances that make observance of isolation or quarantine neither likely nor helpful in preventing secondary or subsequent related cases in the home of

the index case or elsewhere; failure to verify the diagnosis of certain important diseases by an expert clinician, by laboratory test or by both; requiring isolation periods for infected persons and quarantine periods for exposed susceptibles which are significantly inconsistent with the known periods of communicability and incubation of the particular disease; failing to provide for a consecutive sanitary supervision of carriers from the time of the clinical course of the disease, or the first discovery of a carrier state, until it can be shown that these persons are no longer spreaders of infection; use of fumigants for terminal disinfection of some of the bacterial and virus diseases.

It would seem in the interest of respect for medical science and the authority of the health officer that there should be a general and nation-wide uniformity, first of information concerning the natural history of diseases subject to sanitary control, and second, of procedures which involve questions of personal liberty and supervision of the home by the police power of the state.

When one seeks to learn the reasons why in a given local community or state the regulations in effect for control of communicable diseases in some respects are at variance with those accepted by the A.P.H.A., and the three Surgeons General of the federal government, the usual answer is that local regulations are necessarily those issued by the department of health of the state or are actually included in statute law enacted by the state legislature. The local health officer or his board of health only in exceptional conditions, such as those of cities operating under a charter from the state, can make their own regulations independent of those prevailing in the state as a whole. It rests primarily with the state health officer and his board or council to enact such sections of a sanitary code, or persuade the legislature to enact equivalent public health

laws which will be consistent with widely accepted professional opinion. If the state health officer does not accomplish periodic revision of sanitary regulation of communicable diseases to keep practice abreast of the best recent knowledge of the medical sciences, two sources of political pressure can and should be brought to bear upon him or his board or council or the state legislature, namely, that of the organized medical profession of the state and county societies.

It is expected that to keep pace with the advances of medical science, a revision of the report *Control of Communicable Diseases* will have to be made at five year intervals, the next one in 1945. It should be a primary concern of each state health officer and of all independent health jurisdictions with responsibility for enacting sanitary ordinances, rules, and regulations, to review their procedures for control of communicable diseases now to make sure that these are consistent with the information and advice of the latest report of the committee of the A.P.H.A. and to repeat this review and revision periodically following the issue of new editions.

Let me give you illustrations of the extent to which various state regulations conform to the recommended practice:

New York and Connecticut are said to have the best state sanitary codes.

OTHER STATES

State A (Middle Atlantic) (July, 1941)

Common variations from the best practice are an unnecessarily long period of isolation for scarlet fever (30 days or more instead of 21 days) and a period of 10 days for quarantine of susceptibles exposed to a case of scarlet fever instead of 7 days or less. Another error is releasing typhoid fever patients without control tests of feces and urine for the typhoid bacillus. Termination of isolation in typhoid fever, by recovery, death, or removal of patient is not safe and permits easy failure to detect convalescent and chronic carrier states. There is widespread confusion in the use of the terms isolation and quarantine,

which, by the way, are not synonymous. Terminating isolation of a case of chicken pox on the basis of disappearance of all crusts has no scientific or practical basis in fact. The period of communicability is probably not more than 6 days after appearance of the first crop of vesicles, and certainly not more than 10 days, regardless of the date of disappearance of the scabs of skin lesions.

In the state law quarantine of premises is confused with isolation of patients.

State B (Mountain)

Chicken pox isolated for 12 days after eruption and until primary crusts have fallen off. Concurrent disinfection includes boiling dishes and linen. Rigid enforcement of regulations is called for in cases and contacts of chicken pox. It is said that cases may spread the disease as long as crusts are present.

Toys of chicken pox patients may be washed in lysol, dried in the sun, and kept out of circulation for 2 weeks, surely unnecessarily exacting.

Measles is isolated 8 days after the appearance of the rash, although 5 days is known to be the period of communicability after the appearance of the rash.

Non-immune children are isolated and kept under observation for 3 weeks, a practice which is too severe and probably unjustified and unproductive of protection.

Whooping cough is isolated for 6 weeks from development of paroxysmal cough. The Report says 3 weeks is enough.

Placarding of premises is called for where diarrhea of children occurs, and for chicken pox.

Gaseous fumigation of room occupied by a patient with a contagious disease is required where the case terminated in death or the patient was removed before recovery. If case recovers, clothing and upholstered furniture must be fumigated or sunned and aired for 2 days. In the Report fumigation is not advised except to destroy insect vectors.

State C (West North Central)

Chicken pox—Communicable 14 to 21 days until primary scabs have disappeared from skin and mucosae. Placarded. Quarantine until scars are completely healed, at least 12 days from eruption. Report recommends quite otherwise.

Mumps—Isolate until 1 week after disappearance of swelling. Report says mumps is communicable no longer than the swelling of gland.

Measles—Isolated for 7 days after appearance of rash.

Scarlet fever—It is declared to be commu-

nicable 5 weeks from onset, and isolation is at least 28 days.

Typhoid fever—Release on two negative stools. No mention of urine.

Whooping cough—Communicability probably lasts 2 weeks after the whoop. Isolation minimum of 42 days or 1 week after last paroxysmal cough or whoop. Strict isolation. Public funeral prohibited. Report says isolation of children over 2 years of age is impracticable and in even those under 2 should not be insisted upon at the expense of fresh air in the open if weather permits.

State D (West South Central)

Quarantines scarlet fever, diphtheria, small-pox, epidemic cerebrospinal meningitis, anterior poliomyelitis, whooping cough, measles, epidemic influenza, mumps and chicken pox.

Placards typhoid, leprosy, acute pulmonary tuberculosis, venereal diseases (if treatment is refused by known prostitutes). Placarding not regarded as quarantine but merely as notice to the public.

Scarlet fever—Quarantine of exposed susceptibles for 10 days.

Poliomyelitis—Isolation 3 weeks. Report says 2 weeks. Quarantine of exposed susceptibles 3 weeks. Report says 2 weeks. Patient excluded from school and public gatherings 3 weeks after closing isolation. Report does not advise this.

Whooping cough—Isolation until 1 week after cessation of whoop. (About 6 weeks.)

No mention of notification of pneumonia, or rabies, or trachoma.

State E (West South Central)

Includes pellagra and cancer among reportable communicable diseases. Requires insurance company agents (not specifying life insurance) to report communicable diseases.

Meningococcus meningitis isolation required until 1 week after fever subsides. Report recommends 14 days after onset.

State F (South Atlantic)

Publishes as its *Official Bulletin on Control of Communicable Diseases* in 1938 the report of the A.P.H.A. committee for 1936 verbatim. *Reprint 1697*. Good practice and likely to be copied by some other states.

It is suggested that in the interest of approximate uniformity of official procedures for control of communicable diseases this Section, by appropriate resolution, recommend to state and local health officers the practical application

of the facts of medical knowledge upon the natural history of the usual notifiable communicable diseases as these are expressed in the current report of the Committee on Control of Communicable Diseases, and that as this report is from time to time revised to include new facts applicable through administrative procedures and is thereafter approved by the A.P.H.A. and endorsed and published by the U. S. Public Health Service, all health officers modify their sanitary ordinances, rules, and regulations accordingly, or use their official influence to obtain necessary action to the same end by the appropriate legislative body.

Furthermore it is suggested that a continuing Section committee be appointed to report from time to time the extent to which administrative procedures have been made consistent with

the currently accepted and published facts as to the natural history of the notifiable communicable diseases.

Consistency, uniformity, standardization are all qualities of official performance which may either create a false sense of excellence, while in fact expressing no more than a dull and lifeless habit or routine repetition of traditional methods, or may express the coöperative competence of a body of officers of government all equally alert to the necessity of constant adjustment of the authority of the law and the force of public education to the development of new knowledge, and prepared by their professional organizations to use the democratic methods of open discussion and representative committee work to keep their public services abreast of the facts.

Air Raid Medical Administration— Current British Practice*

HUNTINGTON WILLIAMS, M.D., DR.P.H.

Commissioner of Health, Baltimore, Md.

IT was a rare opportunity to be designated by Mayor F. H. LaGuardia, U. S. Director of Civilian Defense, to serve as one of a group of consultants and to go on July 12 by clipper plane as a member of the American Civil Defense Mission to study current British practice in the matter of air raid medical administration.

To fly the Atlantic at 8,000 feet, to set one's watch from 9 p.m. to 2 a.m. in the flash of a second, to skim by at 150 miles an hour alongside of huge inverted pyramidal cloud formations in three dimensions, standing on their points 500 feet high, and with a Grand Canyon in a cloudbank on the opposite side dipping down 2,000 feet toward a dark morocco-leather blue ocean, with its white caps like snowflakes, was surely a fitting introduction to the well known communities of old England that were just catching their breath after the horrible and destructive blitzing of last winter and last spring.

There were six of us on the mission; two city engineers, two police chiefs, a housing and buildings commissioner, and a medical man; each assigned the task of studying the most recent developments in this new and unheard-of type of warfare that may come almost without warning to anyone's front doorstep or office building, including yours or mine. As Mr. LaGuardia has pointed out in quoting from an official bulletin

issued in England in 1938, just prior to the beginning of hostilities:

The need for . . . (these measures for safeguarding the civilian population) is not related to any belief that war is imminent. It arises from the fact that the risk of attack from the air, however remote it may be, is a risk that cannot be ignored, and because preparations to minimize the consequences of attack from the air cannot be improvised on the spur of the moment but must be made, if they are to be effective, in time of peace.

From Mayor LaGuardia to Ambassador Winant to Sir Herbert Morrison, Minister of Home Security at Whitehall, was a rapid and pleasant transition. Mr. Morrison, a man not unlike Mr. LaGuardia in temperament, presides over what would perhaps be our Department of Interior with certain added functions, particularly the national and local police and a large part of the air raid first aid medical services. Other related work, especially the emergency hospital program for the care and treatment of air raid casualties, belongs within the scope of the neighboring Ministry of Health, close by, indeed next door at Whitehall, under the shadow of the cenotaph that commemorates the dead of the last World War.

Mr. Morrison turned us over to Wing Commander John Hodsoll who, since long before Munich and Dunkirk, was assigned to captain what has developed into the most marvelous civilian army that defends the home front and cares for the wounded during and after the blitz. Hodsoll, the best type of British civil servant, conscientious, patient, and

* Read before a General Session of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

kindly, introduced us into the intricacies of the Air Raid Precautions Department (known in England as the A.R.P.) in the Ministry of Home Security. This corresponds to what is now being built up in this country under the term Civilian Defense. Hodson described carefully that a blitz was aimed to destroy the morale of the people and that the work in civilian defense is primarily to preserve and enhance the people's morale. All of the A.R.P. services are aimed at supplying, as promptly as possible, the human needs of the victims of the blitz. These needs, of course, include medical needs, such as first aid, ambulance and hospital services. They take their place side by side with the work of the air raid wardens, the police and fire and rescue and gas decontamination and billeting officials and trained workers, and in close collaboration with a multitude of allied A.R.P. personnel, some full-time, some part-time, some paid and some volunteer, who man the report centers and the control centers and the roof watching points and the community and industrial blackout services; all in the vast British A.R.P. army.

In carefully printed detail the U. S. Office of Civilian Defense in Washington had already secured the experience of the British officials and it was our duty to review this work on the spot and with an eye to most recent modifications and developments in selected special fields. There was practically no bombing in England during our month in that country; so what we saw was prior destruction and the tired army of civilian defenders getting their breath, keeping in practice, recruiting their strength, and preparing for future onslaught. We were all struck with the superb morale and ability "to take it" of the British people, with their oft-repeated expressions of gratitude for the essential assistance they were receiving from the United States, and their bull-

dogged insistence on the rightness of their cause and their certainty that together we would win.

While other members of the mission were busy in Scotland Yard or studying communal and individual shelters against the blitz, and the engineering problems of "protecting" basement quarters for sleeping and housing the A.R.P. army, and the reënforcing of basement hospital operating rooms and allied report and control telephone centers and lines of communications, as well as the questions of the water mains and sewer lines, gas and electric community and regional utility services, I slowly absorbed the differences between such items as a First Aid Party, a First Aid Post, a First Aid Depot, and a First Aid Point. Besides these, attention was given to the duties of the Stretcher Party, the Ambulance Party, the Rescue Party, and the work of the Incident Officer, the work of the Incident Doctor and the other medical units that fight in this backyard trench of a modern blitz war.*

The very choice of the word "Incident," which is the official designation carefully selected when reference is made to the site of a "bombing" shows the pains with which the psychology of the problem of preserving civilian morale has been approached in England. The First Aid Party, of course, is a group of four trained workers under a trained leader, whose task it is to render first aid treatment either at the incident or at a First Aid Post, which is a carefully prepared and "protected" spot where the wounded may be taken by the Rescue Party or by a Stretcher Party. The First Aid Depot is where the First Aid Party sleeps and rests to recover from its fatigue; for we must not forget that London underwent at

* For a good description of the blitz from the human side (the A.R.P. workers and the victims), see a recent volume entitled "Digging for Mrs. Miller" by John Strachey, a London air raid warden. Random House, publisher, New York, pp. 150, \$1.25.

least sixty continuous nights of bombing, and all the A.R.P. personnel must have places where they can recuperate and sleep. And then the First Aid Point was finally discovered and identified as a rural First Aid Post, at a cross-roads farm or store where one could find a trained worker with some bandages and a stretcher and a telephone in case of need, so that an ambulance might be called to take a casualty to the nearest hospital.

One of the more recent developments in the First Aid service is what is known as the "Incident Doctor," usually a man in private practice called by the air raid warden from a roster to circulate in his district from place to place where there may be wounded persons at an incident. He leaves a nurse or nurse's aide at different strategic points and makes his rounds, encouraging those who have not yet been taken in ambulances to rest centers or hospitals. We were told that such a medical man was invaluable in enhancing the morale of the wounded.

In the Ministry of Health, Professor Fraser, Chief of the entire emergency medical service, and Chief Medical Officer Sir Wilson Jameson, were extremely gracious in supplying the most recent printed and circular directions and instructions for the medical services associated with the blitz. These in large number have been brought to Dr. George Baehr, Chief Medical Officer of the U. S. Office of Civilian Defense, for his use in planning for similar services in this country.

Professor Fraser pointed out that the first essential in organizing emergency medical services for civilian defense was that these should be thoroughly elastic so as to be able to meet unexpected needs. He described the superb nationwide acceptance of the theory of mutual aid, where one community comes to the assistance of another when the latter has more of a blitz than it can handle,

or one portion of a community comes to the assistance of another portion, in prompt response to telephone requests. He described the difficulties of evacuating children from families in cities out into rural areas, and indicated that the last word had not been said on policies of this kind, most difficult indeed of determination. He made it possible for us to study the organization of the complicated ambulance service, including ambulance trains such as those capable of taking wounded armies from the coast after Dunkirk, and the ambulance busses like our Greyhound busses in large numbers, reconditioned for special inter-hospital stretcher service, and then the use of ordinary trucks or motors equipped for ambulance duty. Through his kindness it was possible to see the organization of one of the great hospital sectors which serves London. This included a detailed review of the problems of evacuating hospital beds from the center of a great metropolis outward into the rural country by stages over a distance up to fifty miles; with the transformation of peacetime hospital administration so that government and volunteer hospitals were unified under a single Sector Chief, operating by a telephone control service. Such sector arrangements weld together as many as thirty institutions to meet the needs of the blitz. A visit was paid to a large mental hospital that had been transformed into an even larger surgical casualty receiving hospital in a rural area, and to another large rural hospital that had been "upgraded" by the addition of about ten fairly large wooden bungalow shack wards that were necessary to meet the special needs of the blitz. And we learned of the great difficulty in securing needed staff and equipment for hospital and other related services.

It was possible for us to study these intricate problems of civil defense not only in the great metropolis of London,

but also in other smaller cities north and south and in rural areas where the blitz had left its mark of destruction and where we found the A.R.P. army training and practising for future encounters with the enemy. In some we saw large hospitals razed to the ground, and warehouses, business areas, and the homes of the working people all bearing mute testimony to this new and terrible method of attack.

The first aid and nursing and medical and ambulance personnel in the A.R.P. army were, to a large degree, on a part-time basis and on part-time pay. Some physicians received annual salaries and some were paid on a fee basis. There was a skeleton corps of full-time workers on full pay and a large number of non-paid volunteers. The costs, for the most part, were borne by the national government through grants in aid to the local authorities. The satisfactory relationships existing between the Home Office in Whitehall (through the regional directors) and the local authorities was most gratifying to observe. Then too, the use by the national government of the best brains for research study at a special laboratory near Oxford was indeed heartening and profitable. The determinations of medical significance affecting A.R.P. policies were being placed by this laboratory at the disposal of the Ministries in London, as well as being made available to the national medical research councils of the United States and Canada.

As a health officer it was a bit distressing to me to notice that this great task of administering the local emergency medical and hospital services for the current war was often assigned to the medical officer of health of the community. In England it appears to have been customary to overload local health departments with administrative cares and duties such as hospital administration and medical care and other such

work so that the essential preventive duties of a health department, for which it was originally created, are to some degree starved by lack of available time and attention and budgets. Here in the matter of medical and other A.R.P. services for civilian defense in a blitz war, this pattern has again been frequently followed with an unfortunate decrease of health officer attention to many primary duties and responsibilities. The result is, in part, large numbers of children and others unprotected against smallpox and diphtheria, large volumes of unpasteurized milk in urban communities, little or no industrial hygiene as health department work, and syphilis and tuberculosis far from where they could be so far as adequate community control is concerned. It would seem unfortunate if we did not learn, in this country, something of value from these lessons.

Dr. Jameson and Dr. Parran and Dr. Eliot have discussed the great problems of fatigue and nutrition and communicable disease control in the public health picture of Great Britain during this war, and have included the matter of government subsidies for milk and the national wheatmeal loaf of bread containing the entire vitamin B complex. Because such subjects have already been covered, these remarks must limit themselves to the matter of air raid medical administration.

No discussion of this type would be complete without some comment on superb service rendered by the women in England during the blitz war. In all capacities they serve side by side with the fighting forces and with the civilian defense army. In an address to a large gathering of the latter held in London last July, Sir Ernest Gowers, one of the metropolitan leaders in A.R.P. work, included the following tribute which I should like to share with you:

... I do not like, on occasions such as this, to pick out any classes or services for special

mention. All alike have shown the same qualities; London's debt is to all alike. But I must make one exception to this rule. I must pay a special tribute to the women. Their part in the battle has been one that is new for women, one for which women used not to be thought fitted—that of sharing with men the dangers and terrors of the front line. You all know the immortal laurels their heroism has won. I was talking, for instance, only yesterday, to a Chief Officer of one of our outer Fire Brigades for whom the outstanding recollection of one of our worst fires will always be the behaviour of the girls in the mobile canteen. "My God," he said, "they were magnificent. They kept in the thick of the fires; the bombs were falling all round them all night, but they never turned a hair, and always had a joke and a cheery word for our chaps." But there are, I expect, few of you who could not give testimony from what you have yourselves seen many a time. Women have shattered once and for all the curious but persistent illusion of us men that they are less brave than we are, and have placed us in the humiliating position of no longer being able to claim that we are superior to them in any respect. . . .

A personal greeting that I am also most happy to bring to you, the public health workers in the United States, is one sent you by Sir Arthur News-holme, the veteran leader and teacher of public health in England and America. I spent a weekend with him under special government-permit in a war zone area on the southern coast of England, and he asked me to tell all his friends in America that he thinks of them frequently and wished to send them all his very best wishes.

Through Dr. John Grant, a classmate friend back in the early days at the School of Hygiene in Baltimore, I was

guided to a most interesting organization known as P E P (Political and Economic Planning) located close by the Houses of Parliament in London. This association and its monthly bulletin entitled "Planning" * reflect perhaps the best thought for the future among the statesmen and thinkers of Great Britain. Issues of "Planning" have been devoted to "London Under Bombing" (February 17, 1941) and "Health in War Time" (April 29, 1941), and those whom I met in this worth while organization had this to say of the future of their country

The resistance to the best way is gone.

A selfcritical system is good.

There is an acceptance of change.

There is a great impetus given to the discovery of a better way.

In the past the government was criticised for doing something, now it is criticised for not doing something.

There are great promises of future changes. Everything at the present is in a fluid state.

And now the American Civilian Defense Mission must hurry home. It takes a land plane from the United Kingdom to Lisbon, it breakfasts there on August 16, and finds itself at La-Guardia Field in New York at 3 p.m. the next afternoon, and that with two hours out at the Azores and two hours again at Bermuda. It then reports to the Director and to the Chief Medical Officer of the Office of Civilian Defense in Washington.

Silicosis and Other Health Problems of Metal Miners^{*}

WALDEMAR C. DREESSEN, M.D., RICHARD T. PAGE,
F.A.P.H.A., AND HUGH P. BRINTON, PH.D.

*Passed Assistant Surgeon, Assistant Sanitary Engineer, and Associate Statistician,
Division of Industrial Hygiene, National Institute of Health,
U. S. Public Health Service, Bethesda, Md.*

SILICOSIS and other forms of occupational diseases have long been known to occur among workers engaged in the mining of nonferrous metal ores. It is interesting to note that even as early as 1900 cases of silicosis, designated chalicosis pulmonum or chronic interstitial pneumonia, were described among Utah and Nevada metal mine workers.¹ Investigations near Joplin, Mo., in 1914 by the U. S. Bureau of Mines in coöperation with the U. S. Public Health Service indicated a serious problem of pulmonary disease among metal mine workers in that area.^{2, 3} Subsequent investigations suggested a silicosis prevalence of 20 to 25 per cent among mine workers in this same region.⁴

The present report is based on a study of three representative metal mines in the State of Utah, which was made in 1939 by the U. S. Public Health Service in coöperation with the State Board of Health and the State Industrial Commission.⁵ The immediate purpose of the investigation, of which this study forms a part, was to evaluate the various factors bearing on the health of Utah industrial workers, in order to secure information

which could be used as a guide in drafting legislation for the compensation of injury to health resulting from the exposure to occupational disease hazards. The long range objective was to suggest the measures necessary for the control and prevention of the health hazards which were found. Occupational and medical histories and physical and roentgenological examinations were made on 783 metal mine workers (90 per cent of the workers in these mines). Engineering studies were carried out in each mine to determine the environmental factors which might have a bearing on the health of workers engaged in specific occupations.

ENGINEERING FINDINGS

All the establishments studied were underground mines extracting lead-copper or lead-silver ores, in which gold and zinc occasionally occurred in sufficient amounts to be considered as supplementary ores. They were selected to be representative of mining conditions which were cold and wet, hot and dry, and intermediate.

The principal factors to be considered in evaluating the hazard of dust inhalation were the nature and concentration of the dust in question, and the duration of exposure. In the engineering study it was found that underground metal mine workers were usually exposed to dusts containing between 20

^{*} Read before the Industrial Hygiene Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 15, 1941.

* Eight of these samples were collected in ore sampling mills, bucking rooms, and crushing mills operated in conjunction with concentration mills or smelters.

and 40 per cent free silica (Table 1). Since most persons had worked in various locations in the mines where the rock encountered varied from silica-free limestone to nearly pure quartzite, it was possible that at times they had been exposed to atmospheric dusts having a much higher free silica content.

Particle size determinations showed that the dust suspended in the atmospheres of the three mines had a median diameter of 0.9 micron and that more than 96 per cent of the particles were of a size which might readily reach the smallest air sacs in the lungs.

Results of the determinations of the average dust exposure in certain of the more important occupations show that the underground occupations of miners, muckers, hoistmen, tool nippers, chute tenders, and timbermen, and the surface occupations of ore dumpers and buckers, have the highest concentrations of dust. In none of these does the weighted average dust exposure exceed 58 million particles per cu. ft. of air, whereas the numerically most important occupational group, representing 45 per cent of all metal mine workers, namely miners and muckers, showed a weighted average dust exposure of 23.1 million particles based on 139 samples. Approximately 86 per cent of all metal mine workers were found to be exposed to average dust concentrations of between 6 and 30 million particles per cu. ft. About 12 per cent were exposed to less than 6 million particles. High

dust exposures were usually associated with the drilling, breaking, and handling of ore. Ventilation with dust contaminated air in some stopes also contributed to the high dust concentrations encountered in these stopes.

Studies of ventilation and humidity were carried out, and exposure to various gases such as sulfur dioxide, carbon dioxide, carbon monoxide, hydrogen sulfide, methane, and others, was determined. It was found that toxic gases or atmospheres deficient in oxygen were present at times, but that such conditions were of a temporary nature so long as adequate ventilation was maintained. Accidents from this cause could be prevented by constant supervision and inspection of all working places. Extremely high and low temperatures (Table 2), rapid temperature changes, dusts of toxic metals, poor illumination, and inadequate sanitary facilities in the mines and in the surrounding communities were found to be potentially harmful to health in some instances.

A limited number of atmospheric samples which were analyzed for lead content showed that the workers in face operations and skip loading had an average exposure to about 3.7 mg. per 10 cu. m. of air, while other underground operators had an exposure to only 0.2 mg. per 10 cu. m. The high exposure of a lathe operator in a surface machine shop who was using a white lead cutting compound for machining threads is of special significance due to

TABLE 2

the use of this process in defense industries, although it was an intermittent and nonsignificant exposure in the case presented.

Examples of good mining practice with regard to the control of the principal sources of dust indicated that the dust hazard could be greatly lessened

by the proper use of present control measures such as wet methods, adequate ventilation, air cleaners or settling chambers, and local exhaust ventilation.

MEDICAL FINDINGS

The medical study of nonferrous metal mine workers included 783 persons, representing slightly less than one-fourth of the total number employed in this industry in the State of Utah as reported by the United States Census of 1930. All were males and nearly all were either native or foreign born whites. The age distribution of the group studied was similar to that shown in the Census for all Utah metal mine workers.

A detailed analysis was made of the medical examination findings for the 727 workers whose entire experience in a dusty trade had been in metal mines. The remaining 56 persons had previously worked for more than 2 years in a dusty trade other than metal mines; hence, their physical condition at the time of the examination could not be attributed entirely to experience in one industry.

The principal occupational disease found among these 727 metal mine workers was silicosis. As in previous studies made by the U. S. Public Health Service, as well as studies by other investigators, certain symptoms were observed more frequently in persons with silicosis. These included, in descending order of importance, dyspnea, frequent cough, productive cough, chest pain, and weakness. Seldom did all of these occur in any individual worker, but they often appeared in two's and three's, and in combination with other less frequent complaints.

Incidence of silicosis—The incidence of silicosis among workers in the metal mines is related both to the length of their employment in that industry and to the average dust concentration to which they have presumably been ex-

posed during all their working years in metal mines. Table 5 and Figure 1 show the result of grouping the metal mine workers according to weighted average dust concentration in arbitrary intervals of 6 million particles per cu. ft. of air. It will be observed that among the workers studied there were 66 cases, or 9.1 per cent, affected with silicosis. Of these cases 42 were first-stage and 24 were second-stage silicosis. No third-stage cases were observed. Forty-two others were considered as borderline silicosis.

There were only 3 cases of silicosis among the 137 persons who had been exposed, while employed in the non-ferrous metal mining industry, to an average dust concentration of less than 10 million particles per cu. ft. of air. Each of these 3 persons had worked 17 or more years in metal mines and probably had been exposed to much higher dust concentrations during certain periods in the past. Seventeen per cent of the 187 persons exposed to average dust concentrations of 24.0 million particles and over were diagnosed as silicotic. When years employed in metal mines, as well as dust concentration, are con-

FIGURE 1—Relation of average dust concentration and duration of employment in the metal mines to the percentage of workers found to have silicosis (first- and second-stage).

TABLE 5

	{ Per cent with silicosis	9.1	1.0	13.2	30.5

* Includes 2 cases of silicosis among 16 workers with unknown dust concentration.

sidered, the prevalence of silicosis is greatly increased, reaching 37 per cent among those with 20 or more years' experience in an average dust concentration of 18.0 to 23.9 million particles and 68 per cent of those with 20 or more years' experience in an average dust concentration of 24 million particles and over (Figure 1).

Fourteen cases of silicosis, 5 of them with nodular lung-field markings were found among workers with less than 15 years' exposure. Comparatively little dry drilling has been done in Utah during the last 15 years. Yet, if one takes into consideration the dust counts observed during the environmental study, it is apparent that the control methods in present use are insufficient to prevent silicosis. However, if the dust concentration is kept below 10 million particles

per cu. ft. of air, it would appear that the silicosis hazard in these mines would be eliminated.

When employment in nonferrous metal mines is considered from the standpoint of occupation, it appears that the problem of silicosis is most serious for those men working at the face (*i.e.*, drillers, miners, and muckers). Among the group of metal mine workers who had been employed, principally at the face, for 10 years or more, 29.5 per cent were found to have silicosis, compared with 7.5 per cent among all other workers employed for this length of time. Only one of the persons with experience principally above ground was found to have silicosis. He had worked as a blacksmith for 23 years and during that time possibly had been exposed to free silica while sharpening

miners' tools. In addition to face workers, cases of silicosis were found in the five following underground occupations: mule skimmers, powdermen, pipemen, shift bosses, and timbermen.

Figure 2 shows the prevalence of silicosis among 385 persons employed principally at the face of nonferrous metal mines. It will be observed that when occupation remains the same, the per cent affected with silicosis increases rapidly with increasing years of employ-

ment. Whereas approximately a fourth of those who had worked for 6 or more years were affected, the percentage rose to 41 when only those men with 13 or more years of experience were considered. All 4 persons with more than 34 years' experience had silicosis.

From Figure 3, the relative importance among face workers of 3 employment duration groups may be determined. The group with less than 10 years' experience in metal mines, which

FIGURE 2—Percentage of face workers found to have silicosis, classified by duration of employment in metal mines. (Width of bar is proportionate to the total number of workers for the given periods.)

comprised two-thirds of all face workers, had only 1.6 per cent affected with silicosis. The other large group of face workers employed 10 to 19 years, presented a definite problem of silicosis with 22.1 per cent so affected, plus 11.5 per cent diagnosed as borderline silicosis. Three-fourths of the relatively small group of men who had worked 20 years or more had either silicosis or borderline silicosis. From this it is evident that even in a dusty occupation, such as face work, the hazard of devel-

oping manifest silicosis is pronounced only for persons employed over a relatively long period.

Lead poisoning—Lead poisoning ranked next to silicosis as an occupational disease of workers in the three nonferrous metal mines investigated. The health problem as regards lead among these mine workers, like the dust problem, seemed to be essentially one of face workers. Of the 727 metal mine employees examined, 102 gave a past history of acute episodes of lead intoxi-

FIGURE 3—Percentage of face workers found to have first- and second-stage silicosis, classified by duration of employment in metal mines. (Numbers of workers are cumulated downward.)

cation. Nineteen of these men reported episodes within the past $4\frac{1}{2}$ years. The duration of disability in recent years seldom exceeded 2 months and usually lasted only 2 or 3 weeks. The disabling symptoms were predominately of a gastrointestinal nature and were accompanied by a rise in stippled cell count and related erythrocytic changes. No instances of lead palsy or encephalopathy were reported.

At the time of the medical examination, 75 workers were diagnosed as having abnormal lead absorption (latent lead poisoning). Although the sense of well-being in these men was unaffected, each had a combination of 2 or 3 of the signs or symptoms associated with abnormal lead absorption. None was diagnosed as having lead intoxication.

Approximately one-half of the metal mine workers had a lead exposure exceeding the threshold limit of 1.5 mg. of lead per 10 cu. m. of air. The per cent of metal mine workers with exposure beyond this limit increased as the weighted average dust exposure increased. Thus, among all persons who had a weighted average dust concentration of less than 12 million particles there were 9.6 per cent. with a lead exposure beyond the threshold limit. Among those with dust concentrations of 12.0 to 17.9, 18.0 to 23.9, and 24.0 million particles and over, the percentage with lead exposure exceeding the threshold was 21.7, 62.9, and 74.9, respectively. This indicates that if the dust concentration is reduced to safe limits with respect to the hazard of silicosis, the danger from lead poisoning should also be reduced.

Nonoccupational diseases—The physical examination of these metal mine workers failed to reveal any diseases which appeared to be appreciably above the average prevalence found among other groups of male industrial workers. Eighteen metal mine workers had reinfection pulmonary tuberculosis, an inci-

dence of 2.5 per cent. In only 4 of these persons was the disease moderately advanced, while in the remainder it was quiescent, apparently arrested or healed. An excess of complaints of headache among face workers seemed to indicate poor ventilation. A few cases of mild dermatitis were attributable to contact with sulfide ores. The per cent of persons affected with the arteriosclerotic-hypertensive group of heart diseases showed the customary increase with age. Rheumatic heart disease was slightly more prevalent than usual. Only 6 cases (0.8 per cent) of the metal mine workers were found to have latent syphilis, which is less than one-half the estimated rate for the entire State of Utah. Injection of the conjunctivae was observed in 20.8 per cent, nearly the same rate as for Utah coal mine workers.

CONCLUSION

On the basis of the data presented, the following conclusions seem justified:

1. That in these Utah mines the prevalence of silicosis (9.1 per cent) is lower than in certain other areas where lead ores are mined. This is possibly due to a number of factors such as differences in the silica content of the ore and the nature of the mining operations.
2. That while the lead hazard in these mines is not especially acute, there is evidence that lead intoxication still occurs.
3. That if the atmospheric dust in these metal mines is kept below 10 million particles per cu. ft., no disabling silicosis should occur and morbidity from lead may also be expected to decrease.
4. That this reduction in the atmospheric dust concentrations can be accomplished by proper use of present control measures such as wet methods, adequate ventilation, air cleaners and settling chambers, and local exhaust ventilation.
5. That preemployment and annual medical examinations, including a technically good chest roentgenogram, should be made to detect cases of active pulmonary tuberculosis. These physical examinations enable the physician to detect such common ailments as high blood pressure, nephritis, diabetes, syphilis, and heart disease during their incipient stages and to

advise the worker on remedial measures. The annual examinations will also detect early silicosis and thereby call attention to deficiencies in dust control.

Food Poisoning Outbreaks Involving Smoked Fish—Their Epidemiology and Control*

IRVING KLEEMAN, SAMUEL FRANT, M.D.,
AND ABRAHAM E. ABRAHAMSON

Instructor Food Science, Food Trades Vocational High School; Director, Bureau of Preventable Diseases, Department of Health; and Chief, Wholesale Division, Bureau of Food and Drugs, Department of Health, New York, N. Y.

FOR many years smoked whitefish, butterfish, carp and similar lightly smoked and salted fish have been articles of diet regarded as delicacies, particularly by certain nationalities and groups of people. The literature, however, contains practically no reference to either the occurrence of outbreaks of disease following ingestion of this type of fish or the degree to which the various processes of preservation prevent the growth of pathogenic organisms.

The investigation of two such outbreaks again points to the rôle that the epidemiologist, food technologist, and sanitary engineer can play in public health, particularly in preventing food poisonings through the proper processing and handling of food.

The study of these outbreaks indicates a definite food control problem

that may affect large groups of people over a wide area.

FIRST OUTBREAK

During April, 1934, 32 residents of Brooklyn and Queens, and 2 visitors from Newark, N. J., became ill with symptoms of acute food poisoning, vomiting, abdominal pain, and diarrhea. Common to all the patients was the ingestion of smoked whitefish purchased through several retailers from a common wholesale smoked fish establishment in Brooklyn. One of the patients, a woman, aged 49, died two days after the onset of her symptoms, the cause of death being attributed, however, to chronic cardiovascular-renal disease. The remaining patients recovered completely after varying periods of time.

No specific food poisoning organisms could be isolated on bacteriological examination of the remaining samples of fish collected. However, several samples had high bacterial counts, the predominating organism being *Bacillus proteus*. This organism, although not considered pathogenic under ordinary circumstances, when it is found in food of this nature, may very well be responsible for food poisoning symptoms, and

* Read before the Engineering Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

NOTE: Dr. Morris B. Jacobs performed chemical analysis for brine determination and assisted in writing the section on analytical results. Carolyn Oldenbusch and the staff of the Enteric Fever Laboratory performed the bacteriological examinations of the smoked fish samples and stools. Sol Pincus, Deputy Commissioner, gave valuable assistance and suggestions in the investigations of the outbreaks and the writing of this report.

the finding of the organism certainly indicates lack of proper handling of perishable food.

SECOND OUTBREAK

On July 16, 1940, several cases of acute gastroenteritis in Brooklyn were reported to the Department of Health. Within the next few days the reported cases rose to 47, in 18 separate families. Symptoms in all patients consisted of abdominal pain, diarrhea, and high temperature. In some cases, marked prostration occurred, and 6 persons were so seriously ill that they were removed to hospitals.

The others remained at home under medical care. Two of the patients died, one a boy of 5, who became ill on July 13 and died on July 17; the other, a man of 51, also became ill on July 13 and continued to have symptoms until July 28, when he too died.

It was quickly determined that the families affected had eaten smoked fish products purchased in 12 different Brooklyn neighborhood delicatessen stores. From these retail stores the source of the smoked fish was traced to a wholesale smoked fish establishment with retail outlets throughout Brooklyn. The smoked fish in question were whitefish, butterfish, and carp, and had been smoked at a plant in upstate New York, about 100 miles from New York City. It had been distributed both in that vicinity and to retailers in Brooklyn. After remaining in delicatessen stores for varying periods of time up to several days, this product, which is customarily eaten without any further cooking, was sold to persons who came down with symptoms of food poisoning within a few hours after consumption of the smoked fish.

As soon as the source of the fish was traced, inspectors of the Health Department embargoed smoked fish (approximately 1,000 lb.) from this plant found

in the retail outlets. This fish was later destroyed. At the upstate plant, the vats used for washing, soaking, and salting of fresh fish drained directly into a sewer line connected in common with a toilet drain. This sewer pipe emptied into a ditch close to the plant. A sample of the ditch water was found positive on bacteriological examination for *Salmonella typhimurium*.

Thus the stage was well set for contamination of the fish. Once such contamination occurred, and there is little doubt that it must have occurred on many occasions, the growth of pathogenic organisms would be uninhibited because of the lack of refrigeration and of a processing treatment designed to sterilize or preserve.

As soon as the first cases were reported, the New York State Department of Health was notified of the outbreak, and an investigation upstate also revealed that similar cases had occurred there.¹ Seventeen additional patients in 13 separate families were reported, making a total for the outbreak of 64 cases in 31 different families. The ages of patients ranged from 2½ to 60 years; there were 39 females and 25 males. Of the 64 patients, 10 were children. Except for the 2 fatal cases, the illnesses lasted for varying periods up to 2 weeks, with uneventful recovery. A typical history of one family involved was as follows:

Mrs. G. purchased smoked whitefish on July 15. The fish had no abnormal odor or appearance; at about 7 p.m. each member of the family had a similar portion. The same night, Arthur, aged 23, developed chills, vomiting, diarrhea, and a temperature of 104° F. The next day at noon, Mrs. G. became ill with similar symptoms; the day following, Mr. G. had acute diarrhea. The latter's condition became worse and he was taken to the hospital on July 18. Here his symptoms gradually subsided, and on July 27 his temperature became normal. In the meantime, Mrs. G. likewise had become worse and on July 22 was also admitted to the hospital, and recovered in 2 days. The third member

of the family was able to continue work in spite of slight diarrhea.

LABORATORY FINDINGS

Chemical examinations of all specimens of fish were negative for inorganic and organic poisons. Specimens for bacteriological examination included stools from patients and from foodhandlers in retail and wholesale establishments; samples of fish from homes of patients, retail stores, and wholesale plants. From all of these sources a similar organism was recovered, *Salmonella typhimurium*, as follows:

Patients (consumers)	14
Patients (retail foodhandlers).....	3
Patients (wholesaler)	1
Processor (not sick).....	1
Fish (whitefish, butterfish, carp)....	5

Salmonella typhimurium was first described by Loeffler in 1892, and classified by Castellani and Chalmers in 1919. It is also known as *Bacillus aertrycke*, *Bacillus pestis caviae* and *Breslau's bacillus*, and its occurrence is widespread throughout the animal kingdom. According to Bergey,² it is a natural pathogen for guinea pigs, sheep, parrots, turkeys, canaries, chickens, ducks, and pigeons, and has been responsible for numerous food poisoning outbreaks. In fact, it is one of the most common food poisoning organisms found in group gastroenteritis outbreaks, and has been described as found in foods such as meats and duck eggs. Smoked fish, however, has not previously been reported as a vehicle for this organism.

In addition to finding *Salmonella typhimurium* in the stools of patients and in the infected food, search was made for it in the stools of the foodhandlers who did not become ill. A processor who had no symptoms at any time was found to have the organism in his stool. A sample of smoked whitefish taken at the out-of-town plant was also positive for *Salmonella*

typhimurium and, as previously mentioned, a sample of water taken from the ditch draining the toilet was similarly positive for this organism.

PATHOLOGY

Autopsy³ on the 51 year old fatal case revealed that the entire gastrointestinal tract exclusive of the stomach had small areas of superficial hemorrhage. There was marked desquamation of the mucosa of the ileum; some areas were a dark greenish brown in color with numerous scattered hemorrhages. There were no gross ulcerations, no lymphoid hyperplasia, and no enlargement of the mesenteric lymph nodes. The large bowel showed moderate congestive changes and small areas of scattered hemorrhage on the mucosa. In addition, there was congestion of the spleen, adrenals, liver, and kidneys. *Salmonella typhimurium* was isolated from the lung.

HOW THE FISH WAS PROCESSED

The whitefish and carp were received at the out-of-town smokehouse from firms in New York City, in fresh condition, packed in cracked ice. These fish were first washed in running water to remove slime and dirt. The butterfish were received frozen and were first thawed in a barrel into which flowed a continuous stream of cold water. After the preliminary processes, the fish were eviscerated by hand and placed in a 10 per cent brine solution for 6 hours at room temperature. They were next hung on small hooks attached to wooden rods for 3 hours to dry at room temperature, and then put into a smoking compartment where drying was continued over burning charcoal at a temperature of about 90° F. for 2 hours. Finally the gas burners were turned on and the heat in the smoking compartment was slowly raised so that at the end of 6 hours the temperature of the smoke chamber was 138° F. The tem-

perature of the fish after this interval in the smoke-house averaged 120° to 130° F. The smoking process was completed by igniting hard wood shavings which glowed for 1 hour. The fish were then removed from the smoking oven, cooled at room temperature for several hours, then graded and packed in paper lined wooden crates. If not shipped out immediately, they were placed in the refrigerator until needed.

The daily mean temperature in and around New York City during the period of the outbreak ranged from 67° to 75° F. with highs of 80° on July 14, and 83° on July 16. The smoked fish were distributed to various stores and hotels in trucks without ice. The sun beat down on these trucks, and in most instances the fish were allowed to remain for several hours in the hot trucks before distribution to the retail stores where there was further lack of the elementary care for a perishable foodstuff. It was a common practice for retail stores to display smoked fish on counters without refrigeration, at times even under bright electric lights. The fish from the up-state plant were also delivered in a non-refrigerated truck to Brooklyn for subsequent distribution to the New York City retail stores.

STUDY OF FISH PROCESSING

Old methods used for the processing of fish are still in use today. Among these are drying, salting and smoking. When originally practised, these processes served to dehydrate the fish and thus inhibit bacterial action. The primary purpose of smoking fish is the preservation of the fish; the secondary purpose is to increase its palatability. The greatest preservative action of the smoking process results from the drying and dehydrating action of the heat, rather than from the bactericidal properties of the chemical preservatives in the smoke. These chemical preserva-

tives formed from the burning of hard wood for the production of smoke have not been completely identified, since different woods and conditions of burning will yield smokes of different composition. Among the substances formed are formaldehyde, wood creosote, phenols, guaiacol and pyroligneous acid in quantities not sufficient to sterilize. All these, together with the soot from the smoke, impart a characteristic flavor to the fish.

Smoking of fish does not sterilize it. In 1934, Griffiths and Lemon⁴ showed that fresh haddock had bacteria counts varying from 14,000 to 860,000 per gm. When these fish were hot-smoked for 4-5 hours at a temperature of 185° F. to 203° F., the counts varied from 0 to 2,100 bacteria per gm. Some samples of the fish cold-smoked at a temperature of 100° F. for 4 hours gave counts which varied from 5,300 to 3,000,000 per gm. It is therefore apparent that a significant destruction of bacteria occurs only when fish are subjected to hot smoke.

In order to determine the bactericidal action of the smoke itself, these investigators hung a brined haddock in a smoke-house which was smoke free, for the same length of time as in the cold-smoked process. This fish gave a bacterial count of over 200 million per gm. The smoked haddock had a count of 62,000 per gm.

To find out whether the hot smoke had any greater bactericidal effect, they heated the fish to 195° F. under the same conditions as if the fish were being smoked, but without any smoke being supplied. These fish showed a final count of 75,999 per gm. as compared with only 104 per gm. on a similar run with smoke. These experiments demonstrated that the smoke or some constituents of it were more effective as the temperature was increased.

The function of salt in the preservation of fish, other than its effect on

flavor, is mainly to abstract water from the tissues, with consequent inhibition of bacterial action. As the fish are salted or soaked in brine solution, water passes from the fish into the brine, diluting it. Simultaneously some salt passes into the tissues of the fish. When the concentration of the salt absorbed by the flesh has become high enough, the cells shrink because of the loss of a portion of their water. For the salt to have some preservative action of itself, its concentration in the tissues should be at least 4 per cent, since it is only at this concentration that salt inhibits the growth of most bacteria and retards enzymic autolysis. Concentrations below 4 per cent have little or no preservative action because all bacteria require salt for adequate metabolism; some bacteria even grow well in a one to two per cent brine solution.⁵

Griffiths and Lemon⁴ in their studies on haddock used a 10 per cent salt solution for brining. To every 25 lb. of fish, 50 lb. of this solution were used. Samples of the fish examined bacteriologically showed that brining with a 10 per cent salt concentration did not materially reduce the number of bacteria present. As a matter of fact, in 8 samples out of 16, the bacteria count after the brining was increased which is not surprising in light of Yesair's work in 1930.⁶ He examined a number of salt samples and found as high as 1,470 bacteria per gm. in salt.

In order to understand the situation as it exists in New York City, certain trade and economic factors in the production and sale of smoked fish in the metropolitan area must be taken into consideration. The consumer in this area, according to the trade, strongly dislikes a highly salted fish product. Furthermore, drastic dehydration of fish in the smoking process produces a low yield of smoked product. Hence the manufacturer tends to decrease the

length of time and temperature of the actual smoking process. Both of these practises minimize preservative action by reducing the dehydration effect which would ordinarily be accomplished by adequate salting and smoking.

In order to ascertain the amount of salt which would be absorbed in fish tissue in the brining process used by fish plants in New York City, a series of experiments was performed. The analyses were performed upon the fleshy portion of the fish, as the best means of estimating this penetration. The analysis for chloride was made according to the following method.^{7, 8}

Chloride expressed as sodium chloride may be estimated by simple titration with standard thiocyanate solution. Weigh 10 gm. of the flesh portion to the nearest 0.01 gm. into a 250 ml. Erlenmeyer flask. Add 25 ml. of 0.1 normal silver nitrate solution and then 20 ml. of concentrated nitric acid solution. If this quantity is insufficient to precipitate all the chloride as silver chloride, add an additional known volume of 0.1 normal silver nitrate solution. Boil gently on a hot plate, until all solid matter is dissolved except silver chloride. Cool, add 50 ml. of distilled water; 5 ml. of a saturated solution of hydrazine sulfate to remove any nitrous acid formed; 5 ml. of a saturated solution of ferric ammonium sulfate as indicator; 1 ml. of nitrobenzene for each 0.05 gm. of chloride; and titrate the excess of silver with 0.1 normal potassium thiocyanate solution until a permanent light brown color appears. Subtract the ml. of 0.1 normal thiocyanate solution used, from the ml. of 0.1 normal silver nitrate solution added to the fish, and calculate the quantity of chlorine as sodium chloride. With a 10 gm. sample, each ml. of 0.1 normal silver nitrate is equivalent to 0.058 per cent sodium chloride.

These results are tabulated in Tables

1 and 2. The fish take up salt, and continue to take up salt as long as they are soaked in brine solution. The brine solution drops rapidly in salt content for the first few hours, and then more slowly. This brine solution also dissolves some protein from the fish. The strength of the original brine solution used in pickling the whitefish was about 11.4 per cent. Analysis of the fleshy portion of three samples of a finished smoked whitefish product showed a salt concentration ranging from 1.8 per cent

one in Kiel of gastroenteritis due to the ingestion of smoked mackerel. The onset of symptoms occurred soon after consumption of the fish. The smoked mackerel were infected with *Salmonella enteritidis*. The source of the fresh mackerel was Denmark, shipped in iced packages to Kiel and other parts of Germany for smoking. The fish had no abnormal odor or appearance when consumed. The clinical picture in the patients was severe diarrhea, vomiting and fever.

TABLE 1

Salt Content of Whitefish on Soaking in Brine Solution

Sample No.	Length of Time in Soak	Strength of Brine Solution Per cent	Salt Content of Fish Per cent	No. of Determinations
BK 105Z	Fresh	11.4	0.08	6
BK 109Z	5 hours	7.1	0.44	4
BK 111Z	7½ hours	4.6	0.58	4
BK 113Z	10 hours	5.2	0.87	4

TABLE 2

Salt and Protein Content of Fish Brine Solution

Sample No.	Sp. Gr. 60° F.	Salt Content Per cent	Approx. Salometer Reading	Protein Content Per cent
BK 104Z	1.088	11.4	45	none
BK 108Z	1.052	7.1	28	0.60
BK 110Z	1.047	5.6	22	1.39
BK 112Z	1.045	5.2	21	1.47

to 2.1 per cent. This concentration, as noted above, is insufficient to have an inhibiting action on the growth of most bacteria in the fish.

These experiments show that under the methods used for brining and smoking in New York City, no great concentration of salt occurs in the flesh of the fish. There is, therefore, little or no preservative action.

PREVIOUS SMOKED FISH OUTBREAKS

A review of the literature reveals no previously recorded outbreak of food poisoning from smoked fish infected with *Salmonella typhimurium*. The only other outbreak reported due to smoked fish was noted by Bitter⁹ who reported

DISCUSSION

Extent of Problem—Smoked fish are consumed in large amounts by Scotch, Russian, German, Scandinavian, and Jewish groups. The figures for production of smoked whitefish and butterfish by states as given by the United States Division of Fishery Industries for 1939,¹⁰ the last year for which complete statistics are available, are given in Table 3.

Hazard—New York City consumes over one-third of the entire annual production of smoked whitefish and butterfish. The importance of keeping such food articles safe for human consumption in and around New York City is manifest. In certain sections

TABLE 3
Domestic Production of Smoked Whitefish and Butterfish

	<i>Whitefish</i> <i>Lb.</i>	<i>Butterfish</i> <i>Lb.</i>
Massachusetts	221,000

	<hr/> 2,758,963	<hr/> 565,720

of the city, these products form a regular part of the diet of many families. To a lesser extent this condition prevails in many other large cities, and is, therefore, a problem of some magnitude from the public health standpoint in other parts of the country.

Changing the operating practices of an industry is a slow process. Persistent efforts on the part of health officials and the coöperation of the more progressive operators have caused food industries to yield to the acceptance of higher standards of sanitation. There seems to be no reason why improved methods and progressive changes may not be expected of the smoked fish industry. With respect to the education of the consuming public, they can likewise be made to recognize the fact that smoked whitefish, butterfish, and similarly processed fish are perishable foods and require refrigeration and the utmost care in handling.

CONTROL MEASURES

There are 14 wholesale smoked fish establishments under Health Department permit in New York City, each of which was carefully inspected for rat haborage, insanitary conditions and equipment, and unsatisfactory operating methods. Each plant was studied

to determine the methods employed in manufacture and transportation of the finished product.

Trucks were examined for refrigeration facilities, and temperature readings were made of storage compartments of each truck. Corrective measures were taken where unsatisfactory conditions were reported, and frequent periodic reinspections were made and a careful control record was maintained. No attempt was made to change the character of the finished product, since the market demands a slightly salted and lightly smoked fish.

In addition, a complete list of 698 retail outlets is on file. Each retail dealer on this list was visited and his establishment inspected. The storage and display facilities at each location were checked, and the internal temperatures of the fish in storage and on display were taken. All dealers were informed of the requirements of the Sanitary Code of the City of New York, that all perishable foodstuffs must be properly refrigerated at a temperature of 50° F. or less at all times.

Good coöperation was obtained from manufacturers and dealers with respect to refrigeration of smoked fish. There still remains the problem of educating

the consumer to the fact that the refrigeration and careful handling of smoked whitefish, butterfish, and similar types of fish is necessary until ready for consumption.

RECOMMENDATIONS

Since lightly smoked and lightly salted smoked fish is perishable, and readily serves as a medium for the growth of pathogenic organisms, it should be treated as such a type of food product, and the carrying out of the following precautions is indicated:

1. The building in which the food processing takes place should be of sanitary construction throughout, with walls, floors, and ceilings made rat-proof and readily kept clean.

2. There should be facilities for sterilization of all utensils and equipment which come in contact with the products, and the cleaning and gutting of fish should be done under a constant and ample flow of potable water.

3. There should be an adequate and suitable sewage disposal system and sanitary plumbing to protect the products. Live stock and other animals should not be permitted on or near the premises.

4. All workers engaged in the processing phases of this industry should have regular medical examinations, including laboratory tests when such are indicated. Cleansing of the hands, especially after visiting the toilet, cannot be over-stressed.

5. Only salt which has been redissolved and purified after an initial mining or crystallization should be used in making up the brine solutions for processing these products.

6. The brining process should be carried out under adequate refrigeration, that is, at a temperature of 50° F. or below.

7. Preliminary drying of the fish prior to smoking should be accomplished as quickly as possible with the aid of rapid circulation of warmed air.

8. Adequate refrigeration of 50° F. or below should be provided at all subsequent stages of storage, transportation, distribution, and retail display.

9. Efforts should be made to educate the consumer with regard to the perishable nature and disease hazards of this type of food.

SUMMARY

Two outbreaks of food poisoning traced to smoked whitefish, butterfish, and carp are described. Bacteriological, epidemiological and public health aspects are discussed, and recommendations for the proper preparation, storage, and refrigeration of this perishable product are offered. Control measures instituted in New York City are outlined.

How Important Is the Dental Health Program?—Nationally? Locally?*

IRA V. HISCOCK, Sc.D., F.A.P.H.A.

*Professor of Public Health, Yale University School of Medicine,
New Haven, Conn.*

THE problem of dental health is a complex and confusing to both professional and lay groups responsible for community programs. An answer to the assigned question "How Important Is the Dental Health Program?" may be influenced by the interest and understanding of persons who discuss the subject.¹ A negative response may suggest a background of experience in which either there was a lack of effort to develop a constructive program or an absence of careful study and wise planning. In either situation, we are reminded of the statement "Religion has failed" when perhaps Religion has not been tried.

There is an abundance of facts to show the need of more and better dental care. The public is aroused by the findings of Selective Service Boards which show that the largest number of deferments due to physical conditions is because of dental deficiencies. Whether the seriousness of such defects is greater than at the time of the previous examinations of drafted men may be open to question. Dental decay is the most prevalent physical defect among school children. Dental defects were the most frequent of physical defects found during examinations for the National Youth Administration.

That the dental conditions of college men are superior to those of the rank and file is noted by examiners for Selective Service. Brekhuis reports,² however, that the freshmen at the University of Minnesota in 1939 had poorer teeth than did those in 1929; there was a significant deterioration of first and second molars, and some deterioration of premolars; in both years, the boys had better teeth than the girls. It is somewhat disconcerting to learn that "these same 1939 freshmen who showed poorer dental health than the 1929 students were certainly not in any worse general health than the 1929 group; in fact, they were perhaps a little better." But there are many factors which influence the health of individuals including not only the dental status, but also early conditions for mental and physical growth and development, protection from communicable disease, and promotion of sound health practices. Consequently attention must be given to both personal and public health in a broad program which embraces maternal and child health, control of communicable disease, sanitation of the environment, nutrition, adult hygiene, industrial hygiene, mental hygiene, housing, and health education.

As recognized by the National Dental Hygiene Association, the problem of dental health is not restricted to the indigent, although this group usually shows a higher proportion of defects

* Read at a Joint Meeting of the American School Health Association and the Oral Health Group of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 15, 1941.

than persons in the higher income brackets. Strusser reports,³ for example, . . . that studies of adolescents and adults on relief showed that 66 $\frac{2}{3}$ per cent needed either one or two dentures to restore masticating efficiency; that dental conditions of white collar workers show effects of neglect; and, referring to conditions of our Selective Service registrants and applicants for enlistment, he states, "If the foregoing is the condition of the cream of the population, certainly the men in the defense program are no better fit dentally, and certainly it must be agreed that serious dental handicaps may affect health and cause loss of time in industry and the concomitant disruption of a well regulated production plant where every man and every hour counts, and especially where every man has his particular job to do."

Much of the problem lies within the average home of the country, as judged by figures from the U. S. Public Health Service:

a. Twenty-two per cent of the people go to a dentist for all or part of the necessary service.

b. Fifty-eight per cent of the people can afford all or some dental service but do not seek any dental service.

c. Twenty per cent of the people cannot afford dental service and may be considered as the dentally indigent for whom service must be provided by others.

Studies show that most children have one or more decayed teeth, and that the teeth of children under 14 years of age are decaying six times as fast as they are being filled. Wisan properly emphasizes,⁴ that without long range and specific objectives, "where dental services are provided by selecting the worst cases, by waiting for tooth aches, and by giving older children the preference, one finds many permanent teeth lost. Studies indicate when dental treatment during the first two school grades is neglected, 7th and 8th grade children show an average of two to three lost permanent teeth per child." On the other hand, in such communities as Hackensack (N. J.) and Clark Township (N. J.), where emphasis has been placed on the lower grades, less than

one permanent tooth is lost for every two children.

In Honolulu, where a carefully planned program of education and service has been conducted for 20 years, extractions of permanent teeth of clinic children in the first 6 grades of school have shown a striking drop, reaching during the past 5 years an average of 5 to 7 per 100 children, while fillings have slightly increased. Furthermore, in 1940, nearly 76 per cent of the 19,614 school pupils enrolled in public elementary schools had their mouths put in "perfect" condition, while 14 per cent were attending dentists when schools closed, leaving only 10 per cent who did not go to dentists during the year. Many of the 10 per cent arrived in the Territory only recently, including children transferred to Honolulu from rural areas where it has been more difficult to obtain dental service. Of the children whose mouths were put in perfect condition, half were attended by private dentists; most of the children still under treatment were going to the offices of private dentists.

A survey of Mouth Hygiene Programs for School Children in cities of the United States was conducted in 1936 by the Cleveland Child Health Association. In 64 per cent, of the 309 cities for which information was clearly given on the subject, the programs were administered by the Department of Education; in 28 per cent, by the Department of Health; in 6 cities there was joint responsibility between these two departments; while the Dental Society or the Parent Teacher Association or private foundations carried the burden in the remaining cities.

In 104 cities out of 354 where dental inspections were made, the dentist was responsible; in 91 cities there was a combination of personnel engaged in this activity; while in 52 the work was done by a dental hygienist; in 41 by a physician; in 64 by a nurse; and in 2

by teachers. Naturally the percentage of children found to need attention varies not only by the type and extent of the program, but also by the type of examination, personnel employed, and grades covered. Procedures and organization vary widely.

In addition to the confusion as to what is embraced in a sound and adequate program of dental health are the questions of cost and of personnel. A recent report by the Economic Committee of the American Dental Association is revealing. In this study of dental needs of white adults in the United States, 55,000 questionnaires were sent to 11,000 dentists of whom over 1,600, or about 15 per cent, responded by returning 7,541 schedule cards. While recognizing limitations of this study, the committee reported that less than 2 per cent of the cases had never previously visited a dentist, that only 3.2 per cent needed no dental care other than prophylaxis, that the average need for males was 4.3 fillings and for females 4.4 fillings (ages 15-19 years 6.8 to 6.5 respectively), that the average need for extractions and for full dentures (closely related factors) increases with age, being in general greater for males than for females, that (varying with income groups from the lowest to the highest) 22 to 44 per cent of the males visited the dentist within the previous year, and that the average length of time since the last visit to the dentist (varying with income groups from the lowest to the highest) was from 3.1 to 1.7 years, the period being slightly longer for males than for females, but not varying significantly by age groups. The committee reported as the average cost of restoring the mouths of white persons 15 years of age and over who go to a dentist, determined on the basis of specific dental need, \$48.96 for males and \$45.43 for females. If these figures are applied to the white population of the United States, the cost involved

would be over four billion dollars; the cost for the city of New Haven where I am directly concerned as a Commissioner of the Board of Health would be over five million dollars.

Let us consider also the cost of a program for children utilizing the experience of Honolulu which has perhaps the most adequate program in the United States. This service was stimulated by the financial assistance of the Strong Foundation which aided in the training of dental hygienists and largely supported the Strong-Carter Dental Clinic. The cost of operation of the clinic in 1940, serving roughly half of the school children treated, was \$53,874, providing for 16,310 dentists' working hours, for 8,548 children who made 34,826 clinic visits. This is exclusive of a comprehensive and correlated program of dental health education conducted by dental hygienists and teachers in the schools.

What proportion of a community health budget should be devoted to dental health? We need more information on this question. In the Boston, New Haven, and Los Angeles County Health Departments, the proportion is around 5 per cent. In New Haven, recommendations of the local dental committee for additions would raise the proportion to 13 per cent. Seven years ago the Board of Supervisors of Santa Barbara County, Calif., reinstated a dental hygiene service for school children at a cost of about \$3,500 per year which seems to be yielding favorable results in supplementing the services of private dentists. The community budget needs in different communities will vary. Furthermore, not only the percentage of the budget but also the total amount provided for all health purposes in relation to resources of the local community and of the state, as well as possibilities for state and federal aid in certain instances, must be considered.

Dental health education programs

should be integrated with the general health education programs for all age and functional groups. Strusser advocates dental health service for children between the ages of 2 and 14, numbering 24,000,000, and, on a long range basis, estimates that it would require a 37,500,000 hour program over a period of years to reach the maximum efficiency for this group and continue the plan on an adequate basis. This would require 25,000 of the 70,000 dentists in the United States working on a basis of 1,500 hours per year. "That does not mean regimentation or socialization. The dental program of the community may include education for all and service only for the indigent or dentally indigent. However, it would take 25,000 dentists that amount of time to accomplish this task whether it were paid for by individual families or by communities for their indigents. Of course, the program would use other personnel for administration, supervision, and follow-up."

If 25,000 dentists were employed for this service, 45,000 would be available for the other age groups numbering approximately 90,000,000 (eliminating age groups below 2 and above 65), or a ratio of 1 to 2,000. But if only 20 per cent of the population go to the dentist in any one year, the ratio would be one dentist to 400 persons. "Eventually," says Strusser, "the program would be entirely preventive and the growth of the profession would be promoted to the extent of providing personnel on a 100 per cent basis, or a ratio of one dentist to 1,000 persons—the same ratio as in military services in peacetime."

An important feature of an adequate dental program is the provision of qualified personnel. There seems to be a difference in opinion among dentists, educators and public health workers as to the place of the dental hygienist. Should the dental hygienist be chiefly an assistant to the dentist, or should she

also occupy an important place in dental health education? What position should the dentist occupy in administration and in health education? Part of the confusion relates to the basic preparation and fitness of those who have engaged in this work, coupled with a changing emphasis in school health programs.

In Honolulu, where the carefully selected dental hygienists have had extensive training in education and in oral hygiene, besides a college background, the hygienists determine the eligibility of all first grade children for service at the dental clinic operated in good quarters at Palama Settlement. The hygienists' examinations in school bring to light unhealthy oral conditions which might escape unnoticed, because many are thus examined who would not voluntarily go to a dentist for periodic examinations; and the educational work done individually at the chair has proved of great value. In the classroom, the hygienist teaches general health habits, mouth health, and nutrition with emphasis on local foods economically and readily obtained. These talks are made interesting by means of charts, posters, models, and motion pictures. In the Territorial Department of Public Instruction 25 hygienists and one supervisor are employed for 164 public elementary schools in the whole area, giving prophylactic treatments and examinations to children enrolled in grades 1-4, with examinations only to children in grades 5-6, in schools of Honolulu. In a number of rural areas self-supporting dental clinics have been established in the schools where needy children have been cared for by dentists of the locality at a reasonable fee. In California, dental health instruction is also usually given by dental hygienists who are well trained for this service.

But conditions and resources vary. For example, a dental health program in the public schools of North Carolina

was instituted by the State Board of Health in 1918, and a Division of Oral Hygiene was created in 1931. Directing its major endeavor along educational lines in the elementary schools this division has, in addition to a director, a staff of school dentists and an educational consultant. The dentists' activities include instruction of children in the classrooms. It should be noted that the school dentists are not only trained in the profession of dentistry, but also in the art of teaching and in child psychology. To reinforce and follow-up their teaching, the dentists have some graded educational material, prepared by the educational consultant to leave with the teachers.⁵ After teaching in each of the elementary grades, the dentists inspect the mouths of all children under 13 years of age, and make necessary dental corrections for the underprivileged children. The parents of the other pupils who need dental attention are notified of this through the mail and are advised to consult their own dentists. For this latter group no diagnoses are made. The teachers classify the children as to their parents' ability to pay for their dental work. The corrective work for the underprivileged children is termed demonstrative teaching. As in most of the counties the dentists can visit each school only once in every two years, the burden of responsibility for teaching mouth health rests with the classroom teachers. Seventy-five of the 100 counties in the state participate, each bearing one-half of the expense of the program, the State Board of Health defraying the other half.

In New Jersey, where Wisan has conducted a carefully planned program for several years, the State Department of Health disseminates educational material stressing the importance of making dental health a specific objective. In order to show how preventive services improved dental conditions, the department has planned five demonstration

programs, aided by local health committees, in a small industrial community, in rural areas, and in a large city. Using these demonstrations as a means of obtaining definite and practical information, the department is confident that in the near future it will be in a position to:

- a. Inform local communities how dental health may be made a specific objective
- b. Give proof of the effectiveness of a preventive dental service program
- c. Inform administrators just what can be considered adequate funds for an effective dental program

It has become increasingly clear that our dental health education programs must include provision for dental service. As stated by Millberry,⁶

Filling cavities in decayed teeth is a commendable procedure, in fact it is the only known procedure which will restore function and aid in preventing the recurrence of the disease. All investigators who have been interested in solving the problem of dental caries, even the nutritionists who once believed that it was just a diet problem, are now agreed that the pit and fissure cavities in the teeth must be filled by the dentist. These represent about 62 per cent of the total number of decayed teeth on the average and caring for them early in the life of the child is the most effective means of tooth conservation. This is not, however, an absolute preventive measure because teeth will decay around fillings just as they will if sound. Our dental health education programs must, therefore, make provision for dental service in the form of examination of the mouth and teeth, mouth hygiene or prophylaxis, filling of cavities in restorable teeth, and extracting those which are no longer useful or are a menace to health.

Twenty-seven years ago dental scientists from various parts of the world prepared addresses to be delivered at the Sixth International Dental Congress scheduled to be held in London on August 4, 1914. While not delivered because of the First World War, these addresses were later published and revealed ambitious plans for universal service for the care of children's teeth

in all civilized countries through some form of organized state service. After 1914 in several countries, not only in some totalitarian states but also under several democratic governments, the government took over, in whole or in part, the task of caring for children's teeth. In 1934, Sir J. A. Young, Minister of Health for New Zealand, wrote in his foreword to a booklet on school dental service, "Recognizing that prevention is better than cure, it became obvious that the surest means of combating this menace (dental disease) to the general health of the people was to begin with the children, and the Government of the Dominion therefore commenced, some years ago (1921), to build up a system of school dental clinics." A progressive drop in extractions resulted.

In conclusion, there is ample evidence to indicate the need throughout the country for a dental health program soundly conceived, adequately supported, and ably executed. Programs have been developed in several areas after careful study and planning which seem to be eminently worth while. A reasonably effective program in most local communities and states, however, is yet to be provided. While recognizing that conditions vary in different localities, much remains to be clarified in regard to essential elements of a community program beyond the recognition in somewhat general terms of the importance of a threefold approach through: (a) extension of scientific dental research, (b) dental health education, and (c) dental service. Adequate dental care includes daily dental hygiene and regular visits to the dentist. To accomplish this goal, there must be constructive long-range plans developed on the basis of determined needs and resources, qualified personnel, and adequate budgets.

Dental educational campaigns apparently fail to reduce the percentage of dental caries unless professional dental care is also provided. In view of the

magnitude of the task and of the relative returns for funds and energy expended, emphasis at the outset should be given to a solid foundation of work with children, gradually extending the age level above and below the first two grades as resources permit. While this is a major community problem, the program should be geared in reasonable balance with other educational, health, and welfare activities. Many local communities and several states lack sufficient financial resources to meet the problem without state and federal aid. One of the subjects for further study is the proper proportion of the budgets to be used for this purpose, in addition to continuing appraisal of methods of organization and administration. The employment of dentists skilled in work with children is essential.⁷ The educational and guidance programs must be increased in effectiveness. Persons engaged in dental health education must have special training for the task, and methods must be periodically evaluated.

Coöperative planning and action should be strengthened through the formation and stimulation of local, district, and state dental health advisory committees or councils composed of representatives of all agencies concerned with this problem. Several national agencies are equipped to render helpful advisory services and to give other assistance.

Both dentistry and public health have made great advances and significant contributions for public good. With further progress in research and in education, the opportunity for improved, and expanded service will doubtless increase. Can advances in the sciences be translated into further social benefits, through the prevention, control, and treatment of oral disease? Will professional groups adjust to their responsibilities and grow in usefulness for social good? Shall we meet our joint responsibilities? It is up to you and me to do our part in the study

and development of this important enterprise.

Shall Public Health Physicians Attempt to Assess Nutritional Status of School Children?*

SUSAN P. SOUTHER, M.D.

Chief, Child Hygiene Division, Ohio Department of Health, Columbus, Ohio

THE answer to the question "Shall public health physicians attempt to assess nutritional status of school children?" will depend on what the individual answering the question considers the ultimate function of the school physician to be; on whether he believes nutritional status lends itself to clinical evaluation; and lastly, it will depend on how fine or exact an appraisal is to be made. It is obvious that an examination of all the problems involved in answering these questions is beyond the scope of this paper. I shall limit myself, therefore, to a brief discussion of why and how I think a public health physician should attempt to make clinical evaluations of the nutritional status of school pupils. The opinions which I have on the subject are based on my own experience in attempting to ascertain the physical fitness of a group of over seven hundred 6 and 7 year old children attending school in New Haven in 1934-1936.¹

Why should the physician attempt to assess nutritional status of school children?

First let us consider why the physician should attempt to assess nutritional status. Ordinarily a physician

has one of two purposes in mind when he makes a physical examination: either he wishes to discover whether disease or abnormality is present, or he wishes to secure information which may be compared with information secured at a previous examination. Likewise the school physician should evaluate the nutritional condition of a school child for one of two reasons: either that he may discover whether the child is suffering from some disturbance of nutrition, or that he may have information which will enable him to say whether the child's nutritional state is better or worse than at some former time.

But, one may argue, why should one attempt to make an assessment or try to compare an assessment made at one examination with that made at another, when we have no accurate and objective means for judging nutritional status at our disposal and when clinicians frequently fail to agree in their judgments. Those who believe that a clinical appraisal is of slight or no value because it is a subjective evaluation and one affected by the experience and interest or even the emotional and mental state of the observer, have many studies to support their contentions.^{1, 2 *} On the other hand, it has seemed to me that in recent years too much stress has been placed on the inaccuracies of the clinical method and too little said

* Read before the American School Health Association and the Food and Nutrition and Maternal and Child Health Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

* An extensive bibliography is found in reference 1.

as to what can be learned, in spite of these inaccuracies, from such an evaluation.

In attempting to make clear why I think a clinical assessment of nutrition is valuable, I should like to point out the value of the physical examination in assessing health and disease. It is a common experience among physicians to discover that when several examine a patient or a group of patients they will not all agree regarding the size or condition of the tonsils or regarding the findings in the chest or abdomen. Because this fact is true regarding the general physical examination, should we consider that such an examination is useless and ought to be discarded completely? I believe most of you will agree that too much valuable information can be obtained from the careful physical examination to discard it—at least until such time as we have a simpler, more accurate, and less expensive method to replace it.

How accurately is the school physician able to evaluate nutritional status?

The argument advanced to prove the usefulness of a general physical examination can also be used to show the value of clinical methods in appraising nutritional status or in diagnosing specific nutritional disorders. The trained and careful observer, for example, is able to recognize rickets with considerable accuracy without resorting to the use of laboratory procedures. Moreover, such an observer is able to appraise fairly well, if he observes a rachitic child over a definite period, whether or not this particular disturbance is becoming more or less severe. While it is true that even the most experienced physicians may disagree regarding the presence of or the degree of rickets, I believe most of you will agree that the clinical method of diagnosis is accurate enough for routine examinations of children. The more

precise laboratory procedures used in diagnosis may be reserved for children who on clinical examination show signs suspicious of rickets or for cases in which one wishes to secure accurate information regarding the severity or progress of the disease.

Perhaps the following illustration will show even more clearly why I believe the clinical method of evaluating nutritional status is valuable, and what I think the limitations of such an evaluation are. The analogy chosen deals with the sense of sight and is, I believe, comparable in a way to the clinical appraisal of nutrition—an assessment which is based in large measure on visual impressions. Most individuals have, for example, learned to distinguish quite accurately the colors red, blue, and a mixture of these colors, violet. If however, we mix red and blue in many different proportions, we will obtain a number of shades of violet with red at one end and blue at the other end of the series. The more we increase the number of shades the more difficult it becomes for an individual to place correctly a given shade in its proper place in the series, and the more disagreement there will be among a group of individuals called upon to identify the same shade. It would seem that we might conclude from this example that while it is possible to identify distinct colors with enough accuracy to make them of use as colors, we cannot break them down into too many shades and still expect the observer to be accurate in his judgment of them.

Just as training enables an individual to distinguish distinct colors and a number of shades of these colors, so training and experience enables most physicians to develop a fairly accurate concept of what can be considered as good, or fair, or poor nutritional status. On the other hand, clinicians not uncommonly find that the more grades

of nutrition are increased or subdivided, the more difficult it becomes for a physician to know whether to place a subject in a certain grade or in one only slightly above or below, and the greater the inconsistency in judgments when several clinicians are asked to assess a particular individual. This illustration tends to show, I believe, that the classification of nutritional states into a few large grades can be done with enough accuracy to make a clinical evaluation a useful tool. We should remember, however, that we should not attempt to show too fine or exact grades without expecting to find a decrease in the accuracy of our judgments.

How can the physician best assess nutritional status?

If we accept the tenet that evaluations of nutritional status should be made, we are at once confronted by the question as to how such estimates can be made more reliable and hence more valuable than they are at present.

Perhaps the first requisite in making a reliable appraisal is to make a careful examination. Such an examination requires time, a requirement which has been ignored so frequently in school examinations that many observers have been led to question whether such examinations were of enough value to continue to make them. It would seem a better health program if the usual hasty routine examinations of school children could be replaced by a more careful examination (allowing at least 20 minutes for the examination) and by follow-up of children who presented health problems or needs. If such a program were instituted, the physician would then have enough time at his disposal to see and to evaluate the various items such as fat, or weight, or history of diet and disease, which must be considered if anything approaching a reliable assessment is to be made.

The second requirement in making a

reliable clinical judgment of nutrition is to be as objective as possible. The amount of fat and the amount and tone of the muscle are perhaps the most objective items in the physical examination and should be estimated with care. Height and weight too are objective items which are of value, especially when they are considered in relation to race and body-build. Items such as the color, the condition of the hair and skin, the condition of mouth and teeth, and the posture are more difficult to evaluate, but even these, if observed carefully and related to the other findings, are useful in the evaluation of nutritional status.

The third requisite for a reliable clinical appraisal is to examine at repeated intervals children who present suggestive signs of nutritional disturbance. Accurate records of weights and heights taken by the school nurse or other trained personnel, and complete records of the physical findings of the physician over a period of observation help us greatly in deciding at any given examination what the physical condition of the child is, and also whether a child is in need of closer medical supervision. For instance, if one were asked to judge the nutritional states of two 6 year old children who presented similar clinical findings, he would be in a position to make a more accurate evaluation of each child if it were known that one had gained only 1 pound in the preceding 6 months whereas the other had gained 5 pounds. In this connection may I stress again the value of using growth records and of comparing a child with himself rather than with other children in arriving at a reliable clinical estimate of a child's physical condition.

The value of the past history

Another valuable asset in making an accurate evaluation of nutritional status and one too little used in many school

examinations is the past history of the child. If school examinations were done only in the presence of a parent or other responsible member of the family, so the examiner could learn whether the child under consideration had been ill or well, or whether he had good or poor dietary habits, or whether he was overactive or inactive, the clinician would obviously be in a better position to make a reliable assessment of the child than if he had no such history. One of the children examined in the study to which I referred at the beginning of this paper demonstrated to me the importance of history and growth records in assessing nutritional status and in deciding whether medical supervision was needed. The child when examined at 7 years of age presented nothing unusual except that his nutrition was low borderline. Two months later he died of a brain tumor. Since nothing was learned at the time of the physical examination that was of benefit to the child, the examination might as well not have been done. However, had I made the examination in the presence of the mother and learned that the boy was having headaches and attacks of vomiting, and had I availed myself of the child's weight record which showed a gain of only 2 pounds in the previous year, I would have had information that would have been invaluable in helping me to arrive at a more accurate assessment of the child's nutritional condition and of his general physical state. In other words, I would have been in a position to know that the boy needed further medical supervision, and I would have fulfilled by this additional information the function for which I assume school examinations are intended.

And finally may I stress the importance of trying to maintain a constant picture of what constitutes good, fair, and poor nutrition, in order that clinical judgments of the item may be fairly

accurate and consistent. Many physicians who are called upon to examine school children have had a wide experience in observing sick children but have had relatively little opportunity to examine the healthy child or to see good or optimum development. And, on the other hand, the physician whose time is given over entirely to school work may forget to what extent physical handicaps or disease may affect the child's well-being. Undoubtedly the accuracy of judgment of both groups of physicians would be improved if each could continuously have the chance to examine and evaluate both sick and well children. Clinicians, too, have observed that if one examines large numbers of children of the same race or of similar social and economic levels his concept of the different nutritional grades may be distorted.^{3, 4} For example, if one examines only children in an area of economic depression, he may see so many poorly nourished children that he begins to think of poor nutrition as being average or usual and of average or borderline as good or excellent. This type of error could, I think, be largely eliminated if physicians doing routine school examinations were not assigned to particular areas in a community but were moved about frequently from one area to another in order that they might see children of different racial and socio-economic groups, and might thereby be able to keep in mind fairly accurate pictures of what constitutes good, borderline, and poor nutritional states.

SUMMARY

1. The clinical assessment of nutritional status of school children should be made since such evaluations, carefully done, are still our best single means of determining the nutritional condition of the children.

2. It should be remembered in using the clinical method of assessment that it is a crude method, and that it does not lend itself

to the classification of nutritional states into too fine grades.

3. The accuracy of the clinical method is increased by making the examination as objective as possible, and by taking into consideration the disease, dietary, activity, and growth history of the child.

4. The present widespread practice of examining large numbers of school children in short periods of time should be abandoned. The practice is not valuable from the standpoint of the children, the school, the parents, or the physician.

Problems in the Laboratory Diagnosis of Rabies*

W. D. STOVALL, M.D., F.A.P.H.A., AND S. B. PESSIN, M.D.

State Laboratory of Hygiene, Madison, Wis.

THE diagnosis of rabies in the laboratory is based entirely upon the microscopic demonstration of Negri bodies and upon animal inoculation. The demonstration of Negri bodies is the method of choice since the diagnosis can be thus made in a few minutes or hours. When the technic employed demonstrates typical bodies the result is highly convincing and satisfying. However, negative and doubtful results leave much to be desired, and animal inoculation must be resorted to. The difficulties in demonstrating Negri bodies arise from two sources of error which can be enumerated as inability to differentiate them from other inclusion bodies and cell structures, and inherent deficiencies in the methods of examination.

NEGRI BODIES, LYSSA BODIES, AND OTHER BODIES

The large Negri body with the inner structure well developed and stained is easily recognized by any microscopist who has seen a few demonstrations. No long years of experience are required since the difficulty lies not in the recognition of the typical body but with its demonstration. Negri¹ described the body as occurring in two forms, one in which the inner bodies are small and highly refractile and another in which they are larger, less refracting, roundish,

oval, or irregular. In one phase of their development the cytoplasm encloses a mass of minute inner bodies which when they are distributed through the central nervous system in single units cannot be differentiated from the granular structure of the cellular elements. Since the identity of the Negri body is not yet understood, its development is not known. However, every experienced microscopist has encountered the difficulty of deciding whether the bodies observed in some preparations are Negri bodies or cytoplasmic structures normal to the cell or if not normal at least only distorted cellular structures. Goodpasture² refers to the variation in size of Negri bodies and speaks of being able to demonstrate the smallest forms. When small bodies are associated with large ones, which show the typical inner structure, no confusion is encountered. When, however, only forms so small occur that the demonstration of the "Innenkörper" is doubtful, the diagnosis is doubtful. The brain of cats, particularly, offers difficulty because of the pink staining granular material in the cells and also because the Negri bodies in the pyramidal and Purkinji cells of this animal are often very small. The failure of the microscopic diagnosis of rabies as proved by mouse inoculation is shown in Table 1.

It is not always because of the size of Negri bodies that satisfactory demonstration fails. There do occur in

* Read before the Laboratory Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 16, 1941.

rabid animals bodies described by Goodpasture² as "lyssa bodies." These bodies differ from Negri bodies in size and the absence of "Innenkörper." They are described as very small, pink staining, homogeneous spheres. They are found with and without recognizable Negri bodies. In those brains containing no unmistakable Negri bodies these bodies are the cause of much confusion in the diagnosis. Animal inoculation is the only method by which the diagnosis in such cases can be made. Because the microscopic diagnosis was indefinite in some cases we injected mice with material from 76 animals which had been reported as Negri-positive or doubtful. As shown in Table 1, only 66 of these animals proved to have rabies by mouse injection. Additional experience with this discrepancy does not assist in its prevention since we find instances where rabies virus is associated in the brain with eosinophilic bodies that are not Negri bodies.

As a result of this experiment we were prompted to examine for eosinophilic bodies the brain from apparently well cows and sheep that were killed at a local packing plant. Sections were prepared from portions of the hippocampus, cerebral cortex, cerebellum and medulla. In the medulla and cerebral cortex we were able to demonstrate large and small bodies which took the eosin stain. These bodies were both intracellular and extracellular. They were for the most part homogeneous but sometimes there was a small dark staining granule in the center. These bodies resemble "lyssa bodies" more than Negri bodies. Since Goodpasture demonstrated that "lyssa bodies" are homogeneous, and since bodies demonstrated in the brain tissue of normal animals and animals suspected of having had rabies have the same homogeneity and staining reaction, even the most experienced observers cannot make a decision without mouse inoculation.

SMEARS—IMPRESSIONS AND SECTIONS

Sellers³ reported that 40 of 46 laboratories questioned about the methods employed to demonstrate Negri bodies used smear or impression. Only 2 laboratories used paraffin sections. When typical Negri bodies are present these preparations are satisfactory. In our experience typical Negri bodies are often scarce and difficult to demonstrate in the brain tissue of hogs, cows, horses, and cats. In paraffin sections hundreds of cells can be examined quickly, and in properly fixed and stained preparations the sections are clear and there is good visualization of the structures of the cells as well as small Negri bodies. The importance of the examination of large numbers of cells from different parts of the brain and cord is emphasized by the wide distribution of the virus in the brain. In a study of 84 Negri-positive brains we found Negri bodies in the cerebral cortex alone in four instances (Table 2). In a com-

Total	84

parison of the direct smear method with paraffin sections we found that in 10 per cent of the cases the sections were Negri-positive when the smears were negative. In no case were the sections negative when the smears were positive.

The chief objection to sections is that they are time consuming and offer more technical difficulties than smears do. However, the delay in the diagnosis occasioned by sections is not significant. At the longest it is never more than a few hours. When the incubation period of the disease is considered, even the

matter of a day is not important. If the acetone fixation described by one of us (Stovall⁴) is used, the sections are ready for examination in 3 to 5 hours. The small pieces of tissue can be left overnight in the acetone but they are ready for embedding in paraffin within 2 to 3 hours, depending upon the size of the pieces of tissue. It is not unusual for us to have the sections ready for examination in the late afternoon when specimens are received in the forenoon. It is our practice to prepare smears as soon as the specimen is received, and if they are Negri-negative, sections are examined before animals are inoculated. The technic is not complicated or laborious, and the equipment is nothing more than is found in most laboratories.

STAINS

In our hands eosin-methylene blue is the most satisfactory stain for the demonstration of Negri bodies in routine diagnostic work. One of us has shown the importance of dissolving the dyes in a solution in which a low pH is maintained. The study showed that 1 per cent eosin (yellowish) in 95 per cent alcohol maintained at pH 6 stains Negri bodies a pale pink; at pH 3.0 the large and small Negri bodies stain a uniform deep red. The counter stain was methylene blue adjusted between pH 5.0 and pH 6.0. As the pH of the methylene blue rises above pH 6.0, more and more of the eosin is removed from Negri bodies until at pH 8 the small bodies cannot be seen and the large and more typical ones are pale and atypical. This destaining action of the methylene blue solution as it approaches neutrality seriously interferes with the visualization of Negri bodies. When eosin and methylene blue are maintained at the optimum pH the cytoplasm of the nerve cells takes a diffuse pale blue color and the body of both the small and large Negri bodies a deep red. The inner structure of the Negri bodies appears as

dark blue granules. In the small ones there is often only one small granule. The "lyssa bodies" are a homogeneous red color.

Sellers⁵ has recommended basic fuchsin and methylene blue in an alcoholic solution for smears and impressions. Because we have found eosin-methylene blue used as described above so satisfactory for paraffin sections, we have also used it for smear preparations.

ANIMAL INOCULATION

Above we have mentioned the occasional occurrence of what appear to be "lyssa bodies" or small Negri bodies in the brain of some animals which did not produce rabies when injected into mice. These bodies are found most frequently in the cerebrum and medulla. Since in the study of 84 cases of rabies proved by mouse inoculation we found Negri bodies only in the hippocampus 8 times and only in the cerebral cortex 4 times (Table 2), the finding of *eosinophilic bodies* in any portion of a brain from an animal suspected of having had rabies creates a doubt as to the diagnosis. In all such cases we have injected mice, as well as in all cases that were clearly Negri-negative. Thus in Table 1 it will be seen that of 354 animals found to be Negri-negative or doubtful only 310 were rabies-negative by mouse inoculation, giving a failure in the microscopic diagnosis of 12.43 per cent. While this is in apparent close agreement with the report of Leach,⁶ it may not be comparable. There are several reasons for this. In the first place the total number of examinations made by us is less than the number made by Leach. Probably more important than this is the difference in the variety of animals represented and the number of each variety.

Sometimes specimens are received that are badly decomposed and for that reason they have been unsatisfactory for microscopic examination.

The intracerebral injection of mice with contaminated brain tissue invariably causes death of the animals from bacterial infection. To avoid this Sulkin and Nagle⁷ investigated a number of bactericidal agents in which they immersed the contaminated tissue. They did not try filtration because reports indicated that this method was unsatisfactory for a health department laboratory. However, we have used filtration through Seitz filters, size No. 3, with all specimens showing contamination or which were decomposed. Mice inoculated with filtrates from typical Negri-positive brains have not failed to develop rabies. The organism which invariably causes purulent meningitis in mice is a small Gram-positive bacillus. We have not had time to work with this organism, and so far we have made no attempt to identify it. In our hands the Seitz filter removes these bacteria and the filtrates are highly satisfactory for intracerebral inoculation of mice.

Small portions of hippocampus, cerebellum, cerebrum, and medulla are emulsified in 10 ml. of sterile saline. If the smears or sections reveal bacteria, the emulsion is passed through the filter and mice injected with 1/100 to 3/100 of a ml.

Of particular interest is the result of mouse inoculations with emulsions from 24 specimens in which small

atypical inclusion bodies were found in the cerebral cortex. In 5 instances the bodies were considered characteristic enough to consider the microscopic examination to be Negri-positive. In only 1 of the 5 was rabies virus demonstrated. The remaining 19 specimens were considered doubtful by microscopic examination. Of these, 9 were rabies-positive and 10 were rabies-negative. From these results it appears that by microscopic examination of sections and in some smears we are able to demonstrate eosinophilic bodies resembling "lyssa bodies" and atypical Negri bodies which are not associated in the brain with rabies virus. Also the results show that brain specimens in which the microscopic examination leaves the diagnosis in doubt contain rabies. The bodies that cause this confusion in the microscopic diagnosis of rabies are similar to ones found in certain parts of the brain of normal cattle and other animals and to atypical or small Negri bodies.

Studies on the Single Injection Method of Canine Rabies Vaccination*

HARALD N. JOHNSON, M.D., AND CHARLES N. LEACH,
M.D., F.A.P.H.A.

*Staff Members, International Health Division of The Rockefeller Foundation,
State Board of Health, Montgomery, Ala.*

IN view of the notable degree of protection against rabies afforded dogs by a single 5 ml. injection of commercial chloroform-treated vaccine containing $33\frac{1}{3}$ per cent brain material, as reported in a previous paper,¹ it was deemed advisable to repeat this experiment. In order to eliminate, as far as possible, variability due to differences in age and batch of vaccines and test virus inoculum, such as occurs when several successive small groups of animals are used for a study of this kind, the experiment herewith reported was undertaken with a single large group of dogs.

The question has arisen in regard to the chloroform-treated vaccine as to whether it was the use of this particular chemical inactivating agent or the high brain concentration which was responsible for the considerable degree of protection obtained by us in dogs vaccinated with this preparation.¹

In order to answer this question we requested a commercial house to provide us with chloroform- and phenol-treated vaccines of identical brain concentration. These were tested in parallel.

Rabies vaccines deteriorate rapidly

when not kept in cold storage. It was thought that freezing and drying the vaccine in vacuum might obviate the necessity of cold storage. To determine this point we also tested chloroform-treated vaccine of the same lot number which had been subjected to freezing and drying in vacuum.

Experimental studies comparing the efficacy of the single subcutaneous method of vaccination with commercial chloroform-treated canine vaccine containing $33\frac{1}{3}$ per cent brain material and phenol-treated vaccine containing 20 per cent brain material have already been reported.^{1, 2, 3} In our experience the chloroform-treated vaccine has proved to be the more efficacious of these preparations in preventing rabies in the dog when given one month preceding an experimental inoculation of street virus. These studies are summarized for comparison with the present experiment.

MATERIALS AND METHODS

As in our previous experiments, the dogs used were purchased from owners and data were obtained as to breed, sex, and age. None of the dogs had been previously vaccinated.

The average age of the vaccinated animals was 17 months, while the average age of the control group was 18 months. The vaccinated dogs had an average weight of 23 pounds as compared to 19 for the controls.

* Read before the Laboratory Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 16, 1941.

The studies and observations herein reported were conducted with the support and under the auspices of the International Health Division of The Rockefeller Foundation and the Alabama State Board of Health.

A total of 135 dogs was used. These were divided into the following groups: 34 which were vaccinated with the liquid chloroform-treated vaccine, 33 which received the frozen and dried preparation, 32 which were given the phenol-treated vaccine, and 36 which remained unvaccinated.

To reduce the occurrence of infectious diseases among the dogs they were kept in small units, with not more than two dogs to a kennel, until they had survived longer than the usual incubation period of rabies. The use of wooden gratings for the floors eliminated clinical coccidiosis infections.

The commercial house which supplied the chloroform-treated vaccine used in a previous experiment furnished the two vaccines employed in this study.

The chloroform-inactivated vaccine was prepared from the brains of sheep killed when prostrate with fixed virus rabies. After homogenization and dilution to a $33\frac{1}{3}$ per cent suspension in normal saline the material was filtered through a wire sieve. Chloroform was then added to a strength of 1 per cent. The vaccine was subsequently kept at refrigerator temperature and shaken for a 10 minute period, three times a day for 30 days. The material was homogenized November 13, 1940. The animal inoculation test for the presence of live virus was performed January 13, 1941, and was negative. The expiration date was given as November 13, 1941.

The phenol-inactivated vaccine was made from the brains of horses killed when prostrate with fixed virus rabies. Normal saline containing 1 per cent phenol was added to make a 40 per cent brain suspension. This material was homogenized, filtered, and subsequently diluted with normal saline to make a final brain concentration of $33\frac{1}{3}$ per cent. The phenol content of the final product was 0.83 per cent.

After homogenization the vaccine was kept at refrigerator temperature. It was shaken three times during the first 24 hours for 10 minute periods and once daily for a 15 minute period for the next 6 days. The vaccine was negative for active virus when tested by animal inoculation 2 weeks after homogenization. The expiration date was given as February 5, 1942. Both vaccines were also tested for active virus at this laboratory by intracerebral inoculation into mice. The vaccines were injected undiluted and diluted 10 fold and 100 fold in broth, tyrode solution, and distilled water. We were unable to demonstrate active virus in either vaccine.

FREEZING AND DRYING

The apparatus for freezing and drying was constructed after the method described by Bauer and Pickels.⁴ The vaccine was tubed in 5 ml. amounts in 25 ml. round bulb Pyrex ampoules. These were subjected to quick freezing in a carbon dioxide ice and alcohol bath. Following this the material was maintained at -25°C . during the entire process of dehydration. This consisted of 72 hours on vacuum and a 24 hour period connected to a phosphorus pentoxide trap. The ampoules were sealed when thoroughly dry with the vacuum partially replaced with nitrogen. The vaccine was rehydrated 12 days after dehydration and used immediately. The rehydrated vaccine was negative for active virus by intracerebral mouse inoculation.

All vaccinated dogs were given a single 5 ml. dose, 2.5 ml. being injected subcutaneously on either side of the cervical spine.

The virus used for test inoculation was obtained from a dog dying of rabies after exposure in nature. This brain had been stored in pure glycerin in an ice cream hardening cabinet at -25°C . for 5 months. At the time of

inoculation the entire brain was weighed and, after thorough trituration, was diluted 1:10 by weight in distilled water. This suspension was centrifuged at about 2,000 r.p.m. for 10 minutes, and the supernatant fluid was used as the street virus inoculum. The test virus was injected immediately after preparation and kept at icebox temperature during this procedure. When all of the dogs had been inoculated serial 10 fold dilutions of the virus-containing material were injected intracerebrally into white mice. By this method the titer was found to be 10^{-5} .

Three groups of vaccinated dogs were given the test virus 31 days after vaccination. The control dogs were tested at the same time as the vaccinated animals. An injection of 0.5 ml. of the 10 per cent test brain suspension was

given into each masseter muscle. Animals surviving the test virus inoculations were held for a period of at least 90 days.

Of the original 135 dogs, 9 died of extraneous causes, leaving 126 for calculation. Autopsies were performed on all dogs dying of rabies and other causes, as well as on those killed at the end of the retention period. The brains were examined for Negri bodies and if none were found a 10 per cent suspension of a pool of various portions of the brain was inoculated intracerebrally into white mice.

OBSERVATIONS

The results of this experiment are set forth in Table 1, which also includes summaries of our previous experiments.

All dogs killed at the end of the 90 day survival period were Negri

TABLE 1

Comparison of the Results Obtained in Four Experiments on Commercial Canine Rabies Vaccines

	Vaccinated			Control			Statistical Significance
	No. of Dogs	Died of Rabies	Per cent Dead of Rabies	No. of Dogs	Died of Rabies	Per cent Dead of Rabies	
Experiment 1 Commercial phenol-treated vaccine containing 20% of brain material, given in a single subcutaneous injection of 5 ml.	105	26	25	120	66	55	0.0000
Experiment 2 Commercial phenol-treated vaccine containing 20% of brain material, given in a single intraperitoneal injection of 5 ml.	52	19	37	63	34	54	0.0933
Experiment 3 Commercial chloroform-treated vaccine containing 33⅓% of brain material, given in a single subcutaneous injection of 5 ml.	50	2	4	55	34	62	0.0000
Experiment 4 Commercial chloroform-treated vaccine containing 33⅓% of brain material, given in a single subcutaneous injection of 5 ml.	32	2	6	36	20	56	0.0001
Frozen and dried chloroform-treated vaccine containing 33⅓% of brain material, given in a single subcutaneous injection of 5 ml.	27	7	26				0.0362
Commercial phenol-treated vaccine containing 33⅓% of brain material, given in a single subcutaneous injection of 5 ml.	31	3	10				0.0002

* By corrected χ^2 test. Likelihood of getting a difference as great or greater than that observed in the mortality of the vaccinated and the control groups by chance alone.

negative, and no virus was demonstrable in any instance by the intracerebral mouse inoculation test.

In the group vaccinated with the liquid chloroform-treated material only 2 of 32 dogs died of rabies (6 per cent); and of the 27 dogs given the same vaccine after it had been frozen and dried in vacuum and rehydrated, 7 died of the disease (26 per cent). Three of 31 dogs vaccinated with the specially prepared phenol-treated vaccine contracted rabies (10 per cent). The mortality rate in the control group as a result of rabies test virus inoculation was 56 per cent, 20 of the 36 dogs inoculated having died of the disease. The percentage mortality in the control group of this experiment is strikingly similar to that of previous studies. This is further evidence of the generally uniform results obtained by this method of test virus inoculation in unvaccinated, control animals if the number of animals tested is large enough to give statistically significant results.

TABLE 2

Variation in Mortality Rates in Small Groups of Control Dogs Following Experimental Inoculation with Rabies Street Virus

Group No.	Number of Dogs	Rabies	Per cent
I	10	3	30
II	10	4	40
III	11	10	91
IV	8	3	38
V	8	6	75
VI	9	5	56
VII	8	4	50
VIII	7	4	57
IX	11	10	91
X	10	2	20
XI	8	3	38
XII	10	6	60
XIII	10	6	60
Total	120	66	55

The principal criticism of the studies on canine rabies vaccines reported in the literature is the lack of sufficient test animals in potency tests using the

same method of vaccination and test virus inoculation. This is especially true of control groups. Table 2 gives the mortality figures for the control dogs in the 13 groups of animals tested in a previous study.² There was a marked variation in the mortality rate in the various control groups, but when these were considered as a whole the mortality rate for the control animals was very nearly the same as that obtained in other experiments (Table 1). This illustrates the variation due to chance, and emphasizes the necessity of considering this factor in planning such tests. When the same experimental procedure is repeated until the total number of vaccinated and control animals satisfies statistical requirements an accurate result is obtained. A good example of this is the almost identical result obtained in our two studies of chloroform-inactivated vaccine. In the one¹ we used repeated, small, approximately equal groups of vaccinated and control animals. The other consisted of a single test of large groups, as reported in this paper.

TABLE 3

Mortality Rate According to Age in 265 Unvaccinated Dogs Following Experimental Inoculation with Rabies Street Virus

Age	Number	Rabies	Per cent
months			
1-6	24	21	88
7-12	121	81	67
13-24	67	33	49
Over 25	53	18	34
Total	265	153	58

Table 3 is included to illustrate the variation in mortality rate of four different age groups of control dogs tested by the same method of inoculation with rabies street virus.

There was no statistical difference in the degree of immunity produced in dogs by chloroform- and phenol-inactivated vaccines when these contained the same concentration of brain material.

SUMMARY

A second experiment to verify results of a previous study of chloroform-treated vaccine was performed. In both instances this type of vaccine produced a high degree of immunity in the dog. The results of the two experiments were practically identical.

No statistical difference in antigenicity was obtained where chloroform and phenol were used as inactivating agents in the preparation of canine rabies vaccine when the brain material was of the same concentration.

The antigenicity of chloroform-treated vaccine was reduced by freezing and drying in vacuum, but it still produced some immunity.

The masseter muscle route for challenge virus inoculation gives consistently uniform mortality results when a

sufficiently large number of animals are employed.

Attention is called to the fallacious results that may be obtained through chance when the number of animals used in a vaccine potency test is not sufficient to rule out error from this cause.

Sewage Disposal Problems at Army Camps^{*}

PAUL HANSEN, F.A.P.H.A.

Greeley & Hansen, Engineers, Chicago, Ill.

THE problem of sewage disposal at army camps differs from municipal sewage disposal practice in several important particulars:

1. Army camp sewage is domestic in character, unaffected by industrial wastes. It is relatively strong and high in grease, as compared with municipal sewage. The per capita flow of sewage is generally less than in municipalities, provided reasonable disciplinary restrictions on the use of water are maintained.

2. Most of the sewage treatment plants at army camps are for temporary use only; that is to say, they are predicated on the assumption that the camps will be in active existence for a period of 5 years. This has a bearing on the economic balance, as between installation costs and operating costs, and implies simple and temporary construction to the extent possible.

3. Speed is an essential factor in the design and construction of sewage disposal works for army camps, whereas municipal installations are seldom of an emergency character and generally can be preceded by adequate preliminary investigations.

Shortly after the program for the construction of army camps was started, it became apparent that the various architect-engineers selected to design and supervise construction of such camps had widely divergent ideas regarding what was necessary for the disposal of sewage. It also became apparent that there was considerable divergence in point of view among the state departments of health in the various states in

which cantonments were being built. To harmonize these divergent ideas, two firms of engineers, Metcalf and Eddy of Boston, and Greeley and Hansen of Chicago, were employed, to act jointly, in reviewing policy with reference to sewage disposal and for the purpose of indicating in general terms the degree of treatment required at each camp. These engineers prepared a report for the office of the Quartermaster General, Construction Division, Engineering Branch. In this report were embodied: (1) a review of the special problems involved in disposal of sewage from army camps; (2) best available estimates of sewage quantities and sewage characteristics, and (3) recommendations for loadings for various sewage treatment devices likely to be used at army camps.

In developing this report, the engineers kept constantly in mind: (1) security to the public health, (2) sufficient treatment of sewage to prevent serious nuisance, (3) economy, and (4) speed of design and construction.

There are several general types of camps as affecting the design of sewage disposal plants; namely, (1) those built in conjunction with permanent army posts, (2) those built in new locations.

Sewage treatment plants for permanent posts are built on a permanent basis, as for municipalities, while those for temporary camps and cantonments are built as simply and cheaply as practicable. A special case arises where temporary camps and cantonments are

^{*} Read before the New Jersey Section of the American Water Works Association at the Seventieth Annual Meeting of the American Public Health Association in Atlantic City, N. J., October 16, 1941.

built in conjunction with permanent posts, as at Fort Knox and Fort Riley. Where practicable, separate installations are desirable for the temporary camps and the permanent posts, as was done at Fort Riley. In some cases this is not practicable. If the permanent establishment is large as compared with the temporary one, a single plant for both may be justifiable. This is the case at Fort Knox. A single plant was established for the entire post utilizing as much of an existing treatment plant as practicable. Division of treatment devices into a suitable number of units will permit latitude in meeting wide variations in sewage flow represented by the entire post and by the permanent post alone. Where the natural outlet for all sewage is in one place and where the temporary establishment is relatively large it may be desirable to build sewage treatment works in two sections—one on a basis for economical permanent operation and the other on a basis for economical temporary operation.

Sizes of the camps, as measured by the number of troops vary from 1,500 to 60,000. The majority, however, range between 12,000 and 36,000 troops.

After a review of all of the available data on sewage quantities obtained during the war of 1917 and 1918, which data incidentally, are meager, the consulting engineers estimated a water consumption of 100 g.c.d. (gallons per capita daily) and a sewage flow of 70 g.c.d. It was realized, of course, that with uncontrolled use and waste of water both the water and the sewage quantities might be greatly increased but it was assumed that sufficient disciplinary control would be exercised to keep the water consumption and sewage flow quantities within these figures without sacrifice of convenience and cleanliness.

Because of the daily military routine which causes most of the population to be doing the same things at the same

time, there are rather violent fluctuations in sewage flow. To provide for this it was assumed that the flow for 3 or 4 hours might average double the average daily flow or at the rate of 140 g.c.d. It was further assumed that peak flows passing through treatment works would be at three times the average rate of 210 g.c.d.

As to the characteristics of the sewage, the meager records of the war of 1917 and 1918 gave little help. Such records as could be found suggested the following characteristics:

	<i>Parts per Million</i>	<i>Pounds per Capita per 24 Hours</i>
Suspended solids	460	0.27
B.O.D. (5 days)	290	0.17
Ether-soluble matter	150	0.09

SECURITY TO PUBLIC HEALTH

As indicated, the first consideration in connection with disposal of sewage at army camps is security to public health. On this point there can be no compromise.

Public health is initially protected in all of the camps by the use of sanitary sewers only. Surface drainage is removed in ditches, through culverts and occasionally in relatively short covered drains. Thus there is no mixed sewage and storm overflow whenever there is rainfall, and therefore all sewage carrying infectious material may be passed through treatment works. While treatment works have by-passes, these are not used except during unusual emergencies. Duplicate units will always permit some treatment both primary and secondary. Even when by-passing, the sewage may be heavily chlorinated.

Public health may be affected by any one or all of the following uses of the receiving body of water: (1) for public water supplies, (2) for bathing and boating, (3) for maneuvers including fording, crossing in small or improvised boats, bridge building, etc., (4) for shellfish layings, or (5) for watering of dairy cattle.

Protection of Public Water Supplies—

There are no instances where it was impossible to find an outlet for sewage reasonably remote from water works intakes. In some instances, there are downstream intakes so far away that self purification is adequate to avoid undue burden on water purification works. An additional factor of safety is afforded by chlorination of the final effluent, which is required in all cases for other reasons than the protection of water supplies.

*Bathing and Boating—*In but few cases was it necessary to discharge sewage from army camps in close proximity to places normally used by the public for bathing and boating. Where such recreational uses exist, chlorination of the final effluent is adequate to protect public health. In a few instances, a relatively high degree of B.O.D. reduction and clarification was sought to avoid any unsightliness.

*Maneuvers—*A number of streams into which sewage effluents are discharged are within maneuver areas. In ordinary fording in mechanized equipment, in horse drawn vehicles, or on horseback, there is little danger of acquiring a communicable disease. Even fording by foot soldiers, if necessary, is not a serious danger. Perhaps the greatest danger is when men fall into the stream, especially a deep one. All reasonable requirements for maneuvers may be met by an effluent that does not look bad, that does not smell bad, and which is also adequately chlorinated.

*Protection of Shellfish—*Along the coastal regions, sewage may pollute commercial shellfish layings. Any effluent that will prevent objectionable odors or unsightly conditions may be made harmless to shellfish layings by adequate chlorination. Because of the use of sanitary sewers, army camps are less of a hazard to shellfish than is sewage from a municipality having combined

sewers, even though the municipality has sewage treatment works.

PREVENTION OF SERIOUS NUISANCE

The degree of treatment necessary to prevent serious nuisance may be and was subject to rather wide divergence of opinion. The word "serious" implies the permissibility of some nuisance. Generally speaking, it was assumed that some discoloration, some turbidity, and an occasional slight odor would not be serious. Cases varied, however. In some situations the effluent outfall was just above a much traveled bridge, a cluster of dwellings, or otherwise frequented places. In these situations, more thought was given to the suppression of odors and any visible evidence suggestive of sewage than would seem necessary where the receiving stream is remote from habitations and frequented areas.

Application of chlorine to the final effluent provides considerable latitude of control over nuisance, as well as being a safeguard to public health. Suitable chlorination of an effluent will retard putrefactive decomposition until the sewage effluent passes critical points, such as a much used bridge above mentioned. Decomposition may in some cases be retarded by chlorination, so that reaeration and dilution may take place more rapidly than the absorption of oxygen. Thus, a condition of non-odorous aerobic decomposition is maintained.

While the consulting engineers recognized that cases might occur which called for a high degree of treatment, stress was placed upon the minimum initial expenditure that would give acceptable results.

DEVICES AND LOADINGS

As a result of the considerations outlined, the consulting engineers recommended that when the minimum average monthly flow in the receiving body of water is 4 cu. ft. or more per second

per 1,000 population contributing sewage in the general locality of the camp, screening, sedimentation, and chlorination will suffice. For flows less than this in the receiving body of water, the consulting engineers recommended biological treatment embodying standard rate trickling filters, high rate trickling filters, or activated sludge, as required by local conditions. High rate trickling filters on account of lower costs with final chlorination were regarded as adequate, even where dilution is very small, or at times reduced to zero, unless there exist local conditions of a special nature demanding a higher degree of treatment.

A typical sewage treatment plant might include the following elements:

Bar screens—hand cleaned

Measuring devices, with simple automatic recording instrument, such as a weir, Parshall flume, Palmer-Bowlus flume, but not a Venturi meter

Preliminary sedimentation tanks

Biological treatment, using high rate trickling filters with recirculation of effluent

Final sedimentation tanks

Chlorination equipment, with contact time in final sedimentation tanks, in separate contact tanks, in a lagoon or in an outfall sewer

Sludge disposal structures, comprising digestion tanks (generally heated), sludge pumping station, and sludge drying beds or sludge lagoons

With minimum dilution during a driest month of 4 cu. ft. or more per second per 1,000 population, the biological treatment and final sedimentation tanks would be omitted.

Loadings on the several devices were recommended, as follows:

Primary Sedimentation Tanks—Three hours displacement on basis of average flow. With effluent from high rate filters recirculated to the inlet of the primary sedimentation tanks, the volume of the tanks would be correspondingly increased. Where activated sludge is justified, the displacement period in the primary sedimentation tanks may be reduced to $1\frac{1}{2}$ hours.

Trickling Filters—For high rate trickling filters not over 3,000 lb. of B.O.D. per acre-foot per day, or a population load of 35,000 per acre-foot. This is applicable to southern camps. For northern camps, a more conservative population loading of not over 30,000 per acre-foot was recommended.

For standard rate trickling filters, where justified, a maximum population loading of 5,000 per acre-foot for southern camps and 4,000 per acre-foot for northern camps was recommended.

Final Sedimentation Tanks—A flow not to exceed 800 gal. per sq. ft. per 24 hours, based on average flow, and not less than $2\frac{1}{4}$ hours displacement period. With recirculation of effluent of final tanks to influent of high rate filters, the capacity would be correspondingly enlarged.

Sludge Digestion Tanks—Two to 3 cu. ft. per capita with heated tanks. For unheated tanks, add 25 per cent to 50 per cent to the capacity, using the larger figure for locations close to buildings. For plants using activated sludge, increase these figures by 50 per cent.

Sludge Drying—For standard sand drainage beds, use 0.5 to 1 sq. ft. per capita for dry southerly climates, and 1.0 to 1.5 sq. ft. per capita for humid northerly climates. In warm dry climates in favorable locations, lagoons may be used with areas of 2 to 3 sq. ft. per capita.

ATTITUDE OF STATE DEPARTMENTS OF HEALTH

Some engineers of state departments of health appear to regard this policy and the plant loadings outlined as too lenient. They feel that, having labored to educate the public to demand clean streams, adoption of lower standards of treatment on the part of the United States Government at army camps will undo much of the good work that has been accomplished after years of educational effort in their respective states.

They believe that the federal government should not act to tear down standards, but should act to build them up; and that the most complete methods of sewage treatment, practicable of application, are none too effective at best and should be used when dilution is small.

The opposing attitude is that cantonments, being of a temporary character, do not warrant elaborate treatment, and that any treatment which does not cause serious nuisance and which protects the public health is sufficient. It is also argued that the country is at war when not a dollar should be spent for superfluities.

ECONOMY

Broadly speaking, it is better to incur large operating costs for temporary camps, than to spend large sums of money on initial installation. The liberal use of final chlorination, while somewhat costly in operation, makes it possible to get along with less biological treatment than might be required for permanent installations in municipalities. Not only may chlorine be used to retard decomposition, but it may be added in amounts that may result in some direct oxidation, where and when necessary.

The question of economy has already been touched on incidentally in discussing other objectives of sewage disposal from army camps. Three factors relating to economy may be stressed:

1. A desire to expend the least total money necessary during the existence of the camps to protect the public health and otherwise obtain acceptable sewage disposal.
2. Recognition of the fact that relatively high operating costs may be incurred for the short period during which the camps may be used, as a means of keeping down total costs.
3. Recognition of the fact that sewage disposal contributes but little to a successful defense effort.

With these criteria in view, the consulting engineers leaned toward rela-

tively high loadings of sewage treatment devices, the use of high rate trickling filters, with recirculation of the effluent, where secondary treatment is needed, and the elimination of final or polishing treatments. It sometimes happens, as in at least one instance in New England, where a high degree of treatment on intermittent sand filters proved to be the economical treatment, because the sand was already in place and required but little labor to put it in condition to receive sewage.

SPEED IN DESIGN AND CONSTRUCTION

An important factor in connection with army camps is speed in design and construction. It was deemed important to have sewage treatment works in readiness to function as soon as troops arrived. Design was directed toward simplification of construction and the reduction of quantities of materials to a minimum. To this end, any devices requiring complicated reinforced concrete were discouraged. For example, sedimentation tanks with mechanical removal of sludge were preferred to Imhoff tanks, even for relatively small installations, because of the more or less complicated concrete work and deep excavation inherent in Imhoff tank construction. Mechanically operated and cleaned screens were discouraged, because of their cost and the rather intricate concrete required for their installation. Trickling filters were preferred to the activated sludge process, because of relative simplicity. High rate trickling filters were preferred over standard rate trickling filters, because lesser quantities of filtering and other materials were required. Buildings were made of wood of simple design, except where there was a serious fire hazard. In such cases, the buildings were made of brick. Limited laboratory facilities were provided, and where water supplies needed laboratory control, an effort was made to combine water and sewage laboratories.

Operation of sewage treatment works at army cantonments has not been all that could be desired. No definite provision was made for operation until many of the cantonments were complete. Often the architect-engineers on the job had to make strong representations to obtain competent operators.

The general procedure was to assign the operation of both water works and sewage treatment plants to the Post Detachment. More often than not, the Post Detachment had no one qualified to deal with these problems. In some instances, chemists were certified from civil service lists. Some of these men did good work, but some had little experience or support. Suggestions were made that the operating personnel be taken from civil life, with the expectation that a suitable number of qualified operators might be recruited from existing large sewage treatment plants and water purification works about the country. This suggestion did not progress very far, and in most instances, the architect-engineers were obliged to give a substantial amount of attention to operation of sewage treatment plants and the training of the personnel. Sometimes, the architect-engineers were able to secure the employment of experienced operators.

Recognizing the necessity of a more effective handling of the various special engineering problems in connection with army camps, there was established in the office of the Constructing Quartermaster General at Washington a staff of civilian engineers, headed by F. H. Fowler, comprising recognized experts in various fields, including sewerage. It

is the duty of this group to advise regarding a well coördinated policy and control of both installation and operation of various utilities and structures at army establishments. In the matter of design and construction, the arrangement has been effective, but in the matter of supervision of operation, suitable lines or channels of information and control apparently have not yet been developed, though effective efforts are now being made in this direction. It is difficult, for example, to obtain prompt and reliable information at headquarters in Washington as to performance of the various sewage treatment works, and it seems to be equally difficult for the headquarters in Washington to obtain prompt rectification of any defects, either in design or operation, that may come to the attention of headquarters.

Army personnel at camps is likely to be changing more or less constantly, bringing to bear an upsetting effect on the continuity of management of camp utilities. As operation and management of utilities are essentially civilian activities, and as continuity of control is essential, regardless of the changes in troop personnel, it would seem desirable to man all water and sewage treatment works with qualified, experienced, civilian operators, and this principle has apparently been recognized. The efforts of these operators should be fully coördinated, by a central agency in Washington, using lines of contact which cut across usual military channels and in particular, records should be kept, reviewed and summarized for present control and for future use in design by experienced engineers.

Willingness of Individuals to Be Examined for Tuberculosis*

G. E. HARMON, M.D., F.A.P.H.A.

Medical Statistician, Division of Tuberculosis, Department of Health, Detroit, Mich.

DURING the period January, 1937–May, 1938, the tuberculosis case finding activities of the Department of Health, Detroit, included the canvassing of about 196,000 persons in the low income group. The canvassing was done by the nurses of the Department of Health with the object of getting as many persons as possible examined for tuberculosis. The economic status of the population canvassed was such that very few were in a position to pay for the examination urged by the nurse. The examinations, however, could be had without expense to the individual, provided the physician making the

examination made an official report of his findings, this report being a requirement for payment by the city for his services. This arrangement made it possible to check the reports of examinations against the list of persons visited by the nurses, and thus to determine among other items the degree of response.

Of the total number visited, the information as to age and color was complete for 187,543; and of this number 48,179, or 25.7 per cent, responded.

For the purposes of this study, all persons having a satisfactory x-ray examination of the chest, and all persons having a negative tuberculin test without an x-ray examination of the chest, were included in the group considered to have responded, and to have been examined. Persons to the number of 3,269 having a positive tuberculin

test without an x-ray examination of the chest were excluded on the ground that such persons had not been adequately examined.

The effect of age on the degree of response is set forth in Tables 1 and 2. For both the white and colored populations, the best response was obtained for the age group 5-14 years. Beyond this age group the percentage of response for both populations declined with increasing age. For both populations the response for the age group 0-4 years was less than among the older children. It should be noted that for every age group the percentage of response is roughly twice as great, or more, among the colored as among the white population.

Another question suggests itself, namely, are the age groups in which the response is greatest the age groups in which the case rates for tuberculosis are the greatest? Table 3 presents the information concerning the cases found by age and the number examined for both populations combined. If adult types of tuberculosis only be considered, the age groups of greatest response

were not the ones in which the tuberculosis case rates were the highest. Even if the primary active type is included, and this type occurs in the main in children, the age of greatest response was still not the age in which the greatest relative number of cases were found. Furthermore, the application of the chi-square test to the data of Table 3 for the latter situation, which minimizes the difference in cases found as between the younger and older age groups, indicates that the difference observed between the proportion of cases found in these two groups is significant.

SUMMARY

Two populations, white and colored, have been studied in regard to their response to the suggestion that the individuals included be examined for tuberculosis, with the following results:

1. The response was greatest in the younger age groups, especially the 5 to 9 and 10 to 14 groups.
2. The colored population responded more than twice as well as the white.
3. The age of greatest response was not the age of the highest tuberculosis case rates.

Development of Training Courses for Food Handlers in Texas*

LEWIS DODSON, M.S.P.H.

Sanitation Consultant, State Department of Health, Austin, Tex.

MOST public health workers realize after a few years' experience that basic ordinances play only a minor part in any effort to improve the facilities with and environment under which foods are handled, that it is next to impossible to have an effective supervisory service without intelligent coöperation by the industry and that the success of such a coöperative program depends largely upon the education of the proprietors of food handling establishments and their employees. Having observed the attempts to teach sanitation to the food handling industry by means of individual conferences and demonstrations during routine inspections, the author decided that there must be a more effective way through which this most important function could be exercised.

This problem seemed to present itself in this manner: (A) Who are we planning to train? (B) What are their problems and viewpoint? (C) What do they need to know? and (D) How are we to get this information to them? The answer to the first of these queries is "The owners and operators of food handling establishments and their employees." In answer to "B," suffice it to say that there are many problems in an undertaking of this kind. Training adults who may or may not be recep-

tive calls for attention to factors not present in child training. They are out of practice in the art of learning. Often, too, adults do not have an incentive to learn, and this incentive must be created. Many have but little time to attend classes or meetings. Hence, the frequency and time, as well as length of meetings should be fitted to each group. If regular attendance is expected, the process of learning should be made pleasant. The proper arrangement of seats, sufficient light without glare, ease of seeing and hearing and proper room temperature should all be kept in mind. Learning should be made easy and simple, and complicated problems and formulas should be avoided. Adults may be self conscious about learning new things and are easily scared. This pitfall must be avoided, too. Also, they have opinions and ideas of their own and these should be carefully respected by the teacher.

A brief answer to the item labelled "C" might be "How to handle food properly," but that would not be very helpful to one who has to learn new methods and procedures. Some knowledge of bacteriology is certainly necessary if food handling personnel are to understand the "why" of sanitary procedures. Communicable disease control and the causes of fermentation and decay should follow information on elementary bacteriology. With the discussion of communicable diseases, decay, and fermentation, some exposition of the vehicles, methods and modes of disease

* Read at a Joint Session of the Conference of State Sanitary Engineers, Conference of Municipal Public Health Engineers, and the Engineering Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

transmission should be given. Therefore, some medical zoölogy or at least pertinent data concerning flies, rats, and roaches would be needed to complete the preliminaries and give the food handlers the background necessary to understand the reasons for sanitary rules and regulations. Of great interest to the employer and owner is the loss and wastage of food, and certainly the increasing amount of food poisoning and food infection is of interest to the public health worker. Therefore, the next topic for discussion might very logically be foods.

Disinfection, sterilization or sanitization of utensils is probably one of our greatest problems and should certainly be included in any training course. Another factor in the spread of disease may be the individual food handler himself. Therefore, with some time devoted to personal hygiene and sanitation, we have a program as follows:

1. Bacteriology
2. Communicable diseases
3. Medical zoölogy
4. Foods
5. Disinfection and sterilization
6. Personal hygiene and sanitation

Realizing that a training program would have to be short and even though progress was expected to be made only very slowly, it was decided to limit the first unit to 12 hours.

The last problem is how to teach so that the class might benefit. We decided to use as many teaching aids as possible, hoping that if our information failed to reach the "students" in one form, it would be retained if presented in another. The kind of lantern slides, movies, and lesson material to be used was therefore carefully planned. Experience in other adult classes had shown that two meetings a week was satisfactory to most people, and that 1½ to 2 hours was about as long as the average group would remain attentive. Hence these time limits were accepted. Follow-

ing these preparations, the first school was held in 1938.

First, an easily accessible central meeting place was selected. Classes were held in the afternoon and at night and on alternate days in order to make the work course available to those working day or night. Personal calls were made by the local sanitarians to each food handling place, explaining the course and leaving a program for the school. Several announcements and news articles appeared in the local paper. Every effort was made to get as many food handlers as possible interested. Approximately 800 were finally enrolled and 437 of these received certificates. This first school was held in coöperation with the State Board of Vocational Education and certificates of attendance were issued to those attending 80 per cent of the meetings.

As the success of this first effort became known, health unit directors and engineers began to request that similar schools be held in their cities. As these requests continued to come in, it became evident that additional instructors would be needed. Hence, other itinerant instructors were trained to handle the teaching program. It became evident that even with three itinerant instructors, only a few thousand of the many thousands of food handlers in the state would have an opportunity to attend these courses within a reasonable length of time.

To check the value of this work, surveys were made. These, with letters and statements from employers and executives, convinced us that the course was effective. Officials of state associations of restaurateurs, cooks and waiters had also become interested by this time and were giving their fullest co-operation. Probably the most comprehensive survey of the results was found in the report of the sanitary engineer of a city of approximately 75,000. This showed that in a survey of that city's

food establishments made 4 months after food handlers schools had been held, 91 per cent of the food establishments were complying with city regulations concerning proper equipment for sterilization; also, that proper methods of procedure were being practised in 84 per cent of the drug stores, restaurants and bars as compared with the 15 per cent compliance found in a similar survey conducted prior to the holding of the schools.

In order to intensify the training effort, full-time programs were next inaugurated in the larger cities. This involved the training and employment of a full-time instructor and the starting of a continuous training program for the food handling personnel of the first of these cities, namely, San Antonio. Here it was possible to conduct four series of classes each month, giving training to 175 to 200 students per month. In co-operation with the local director of vocational education, the State Department of Vocational Education, and the City Health Department, a full-time instructor was hired; equipment and mimeograph materials were purchased; and other necessary arrangements completed. When a new program is started, a demonstration course is held for owners and managers only, in order that they may be familiarized with the training that is being made available to their personnel. Following this course, the regular program is inaugurated. Fort Worth was the second city to accept this plan of training.

Even with our itinerant instructors and the full-time teachers in the larger cities, we soon realized that, due to the size of the state, it would be possible only to reach the smaller towns once every 3 to 5 years. Therefore, the next move in broadening the program was to train one sanitarian in each county health unit and to make available to him slides, movies, mimeographed and other material necessary to conduct a

successful course. This move is going forward, and many sanitarians are holding their own schools every 3 to 6 months. Therefore, to date, our program has grown from one school a month operated by an itinerant instructor to many schools each month held either by itinerant instructors, full-time instructors, or unit sanitarians.

Regardless of where the course is held or who conducts it, there are usually two meetings each week for a period of 3 weeks; each class period is from 1½ to 2 hours long; the lessons are taken up in the same sequence, and the same slides, movies, demonstration material and tests are used. However, the individuality of the instructor and the local problems are not overlooked. There is nothing mandatory about the methods of instruction, but it has been found that most satisfactory results will accrue to a program which follows the worked-out plans most closely.

As previously mentioned, all the fundamental methods of teaching are employed. Time is given to lectures which are supplemented by discussion. Printed information is handed out at each meeting and this must be studied if subsequent quizzes are to be successfully passed. Usually all the printed material is combined into a small manual by the student at the end of the course. This, then, is taken up by the instructor at the close of the course to see that all materials are in place and then returned to the student to be kept and used later as a reference. True and false and multiple choice tests are given at five of the six meetings of the course and eight movies are used. Some of these have a commercial aspect and others have been prepared in our own visual education laboratories. A series of 125 stereopticon slides 2" x 2" in size, have been prepared, making it possible for the instructor to use about 20 slides at each class. These are changed frequently and kept up-to-date or

changed to meet particular local problems. Demonstrations are particularly illustrative. For example, one Petri dish containing nutrient agar is passed among the students at the first class meeting in order that they may see and examine it. Then three students volunteer as follows: one lightly touches the agar in a sterile Petri dish with three fingers; one takes a hair from his head and drops it on the agar of a second similar plate; and one coughs into the third dish. These 4 dishes are then put into an incubator at the close of the class. At the beginning of the second class, which is 48 hours later, the dishes are passed among the students for them to note the bacterial growths. Similar demonstrations are made wherever practical in order to impress the students with the reasons for and the necessity of sanitary practices.

Certificates of completion are issued to those attending 80 per cent of the meetings in a course. In the larger cities where courses are being conducted continually and missed classes may be made up, it is necessary to attend 100

per cent of the class meetings. Some cities are issuing wall placards suitable for framing to establishments where employees have all secured school attendance certificates. This not only merits public approval but encourages the proprietor to keep his personnel trained in order to retain the placard.

In the larger cities where full-time instructors are employed in coöperation with the State Board of Vocational Education, an enrollment fee of 50 cents is charged. This fee is paid in advance by the employer or, if by the employee, it is refunded to him upon presentation of his attendance certificate after completing the course. The money thus collected is used to pay for mimeographed materials, movies, projectors, and other items needed to conduct the course.

We do not feel that there is anything unusual or exceptional about this training program. We have found that if the fundamental, practical knowledge is disseminated in a simple and attractive way, the average food handler will take advantage of every opportunity to learn more about his or her job.

New Light on the Relation of Housing to Health^{*}

ROLLO H. BRITTEN, F.A.P.H.A.

Senior Statistician, Division of Public Health Methods, National Institute of Health, U. S. Public Health Service, Bethesda, Md.

NO final word is going to be said today, or for a long time, on the precise effects of housing on health, any more than any final word can be said on other very broad problems, such, for instance, as the relative importance of heredity and environment. Even if we were able to establish precise limits to what we mean by housing and to what we mean by health—on which there can hardly be complete agreement—the interrelation of socio-economic facts with housing, on the one hand, and with health, on the other, would make impossible any clear-cut determination of the effects of housing *per se* on health.

Bad housing is a symptom of low economic status; poor health, to a degree, is another symptom. And, to make matters more confusing, any element of bad housing which we choose to employ as a basis for comparisons stands not by itself, but is an index of bad housing in general. Thus, when I show, as I shall, higher rates for pneumonia or tuberculosis in crowded than in uncrowded households, it is not going to be possible to say that the crowding itself has produced all the excess. Perhaps the excess is primarily due to some other element in bad housing; perhaps it is in part a reflection of inadequate food, or insufficient medical care, or

other deficiencies due to lack of money; perhaps, indeed, in many instances illness has lowered the income of the family so that it is not possible to ascribe the excess to economic factors at all. However, there is a good deal that we can tell the public now about healthful housing.

Good housing is important. It is, I believe, the right of all persons. It would be their right whether or not their health were seriously affected. It is doubly their right since their health *is* seriously affected. For, just because we are not able to evaluate the precise influence of the various elements of bad housing on the occurrence of disease, we are not entitled to come to the negative position that there is no influence. In fact, if under a definition of housing, we choose to include crowding, proper sanitation, playground space, and home environment in general, and if at the same time we choose to include under health the maintenance of a state of physical, mental, and social efficiency, the causative relation becomes quite obvious.

Many examples could be cited to bring out this point, or reference made to such standards as the "Basic Principles of Healthful Housing" of the Committee on the Hygiene of Housing of this Association¹—which in themselves constitute new light on the relation of housing to health. It is my purpose, however, not to list examples, but to present some statistical data, which, although suffering from the limi-

^{*} Read at a Joint Session of the Health Education Section and Committee on the Hygiene of Housing of the American Public Health Association, at the Seventieth Annual Meeting in Atlantic City, N. J., October 16, 1941.

tations just discussed, are still striking enough and new enough to be of interest to you. They are taken from data collected in the National Health Survey, a house-to-house canvass of illness and medical care in relation to economic and social factors, made by the U. S. Public Health Service in 1935-1936 in coöperation with the Work Projects Administration. Information was obtained from a responsible member of the household. The analysis covered $2\frac{1}{2}$ million persons in 83 cities scattered over 18 states. In large cities a random sample of the population was obtained; in smaller cities the total population was covered. I shall not discuss the survey technics further, since they have been adequately described in reports already published. Also I shall not attempt even to summarize all of the Health Survey data collected on housing, which include the extent of poor housing in urban areas and its relation to economic status, color, and other factors.² For the present purpose it must suffice to show a few charts of outstanding findings bearing particularly on the relation of housing to health.

First, let us consider the association of the common communicable diseases of childhood with crowding. Crowding is expressed for this purpose as persons per habitable room, and was calculated separately for each household. The groups used are (a) households with one person or less per room, (b) households with more than one person and not more than one and one-half, and (c) households with more than one and one-half. The percentages of households falling into these three groups were, respectively, 75, 17, and 8. A more severe degree of crowding could have been selected, but the percentage of households in the group would have been less.

It may be stated that some of these diseases, particularly diphtheria and mumps, show very much higher rates in crowded households than in uncrowded

ones; but to save time I have concentrated on perhaps the most striking fact with respect to this category of diseases, namely, the tendency for them to occur at an earlier age in such households.

Hence in the chart (Figure 1) are shown, not the actual rates, but the ratios of the rate in the age group under 5 to that in the age group 5 to 9. Where this ratio is relatively high, it indicates an earlier age incidence. Obviously the ratio will, apart from questions of crowding, tend to be much higher for some diseases than for others (whooping-cough as against mumps, for instance). The bars have therefore been placed on a relative basis, those for the group with one person or less per room being made equal (as shown by the dotted line).

What is seen in the chart is that the crowded households have a longer bar for each of the seven diseases, clearly demonstrating that the cases occur relatively earlier in the crowded households for every one of the diseases listed. The earlier occurrence of these communicable diseases in crowded households is of significance because of the higher rate of fatality at the early ages.

Comparisons of health survey illness rates against degree of crowding have been made for a number of diseases in addition to those shown in this chart, family income being included in the comparisons. To obtain sharply distinguished groups as to over-all housing conditions, we might contrast (a) the low income (relief) group with more than one and one-half persons per room, and (b) the all income group with one person or less per room. On this basis there is an excess for all causes of illnesses disabling for a week or more of nearly 75 per cent; for tuberculosis (under 65 years of age) of 350 per cent; for pneumonia, of 150 per cent; for rheumatism (adults) of more than 100 per cent; and for influenza of 35 per cent.² Clearly, in the light of my introductory comments, all of this excess

FIGURE 1

COMMON COMMUNICABLE DISEASES OF CHILDHOOD

RATIO OF FREQUENCY IN AGE GROUP UNDER 5 TO THAT IN AGE GROUP 5-9.

(FREQUENCY IN AGE GROUP 5-9 = 100)

NATIONAL HEALTH SURVEY, 1935-36

cannot be regarded as due to crowding. In the published reports the data are shown by income, with the necessary explanations; but I suspect we lean over backward when we attempt to make housing comparisons within the same income groups, since, at low income levels, homes which do not show crowding may still be substandard.

For one disease—tuberculosis—an attempt has been made to deal with the so-called “secondary” attack rate in relation to crowding, since the effect of bad housing might be expected to be reflected most clearly in the occurrence of “secondary” cases into households into which cases had already been introduced. Households in which a “pri-

mary” case of tuberculosis was reported as first noticed within 24 months of the day of the visit have been considered. All persons in these households, except those with the “primary” case, have been regarded as contacts, and only persons related to the head of the household are included.

The “secondary” attack rate (expressed in terms of the number of “secondary” cases per 1,000 years of observation) was 43 for the relief group with more than one and one-half persons per room; and 14 for the all income group with one person or less per room—an excess of 200 per cent. In Figure 2, these “secondary” attack rates are exhibited. The rates for the group with

one person or less per room have been assigned bars of the same length to facilitate the relative comparison. In the top section, we have attempted to eliminate the factor of income by adjustment to a standard income distribution. As indicated previously, in doing so we have probably leaned over backward. Hence, this is a conservative statement. For the total group under 65 years of age, the excess in the "secondary" attack rate in the crowded households (with the effect of income eliminated, as described) is not great—under 20 per cent. However, for children it is 80 per cent. You will observe that a series of bars is shown separately for the relief group. The excess is quite marked, both for all ages under 65 and for children.

Although I am attempting to cover a good deal of ground in a short discussion, I cannot help but pause to refer to the continuing significance of tuberculosis. Sometimes we lull ourselves with the thought that it has declined from

first cause of death to sixth, without realizing that it remains today the most important disease cause of death among young adults, and a vast problem from the point of view of cost of treatment as well. In this connection the close association with housing which we have just illustrated is significant.

At this point let us leave the index of crowding and consider the incidence of digestive diseases in relation to the presence of sanitary facilities. The comparison, it is to be remarked, is still confined to urban areas. Substitution of sanitary facilities for crowding as a classifying item does not change the approach as much as one might think, since there is a marked association between the two; however, it did seem that, in the case of digestive diseases, a slightly more direct comparison was possible by the use of this index. Accordingly the households have been classified on the basis of whether they had an inside flush toilet for their exclusive use. Households with "com-

FIGURE 2

FIGURE 3

DIGESTIVE DISEASES

★ FREQUENCY (PER 1000 PERSONS) OF CASES DISABLING 7 DAYS OR LONGER DURING 1 YEAR

NATIONAL HEALTH SURVEY, 1935-36

munal toilets" or without inside flush toilets at all formed the other group (see Figure 3).

The diseases have been classed in three categories: indigestion and similar stomach ailments; diarrhea and enteritis; typhoid fever. The rates will be the annual frequency of cases disabling for a week or longer. It will be noted that the actual rates are given in the column of figures. As in previous charts, the relative excess in poor housing has been shown by the use of ratios—here the ratio of the rate in households without private inside flush toilets to that in households with such facilities.

The greatest excess appears for typhoid fever; but both of the other groups show a significant difference. It may be stated that a further group of diseases of the digestive system, not

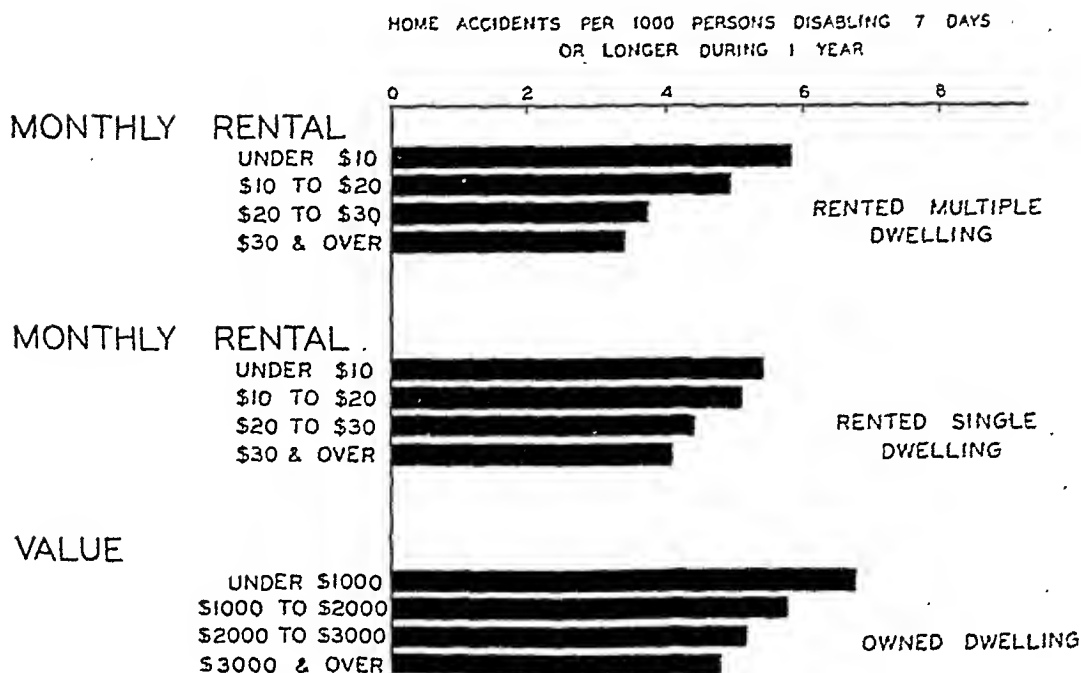

expected *a priori* to bear a relation to sanitary facilities, did not as a matter of fact show such a relation.

Although one is not able to say that all of the excess observed in this chart is due to the lack of private inside flush toilet *per se*, the data suggest that a large part of such excess may be.

Finally, as to home accidents. The illness record of the Health Survey included accidents which had caused disability for a week or more during the 12 months prior to the day of the visit, and the enumerator was required to determine for such accidents whether they occurred in the home. Some information on type of the accident (fall, burn, etc.) was also obtained. For the present discussion, I am confining attention to the frequency of such home accidents in relation to monthly rental

FIGURE 4

HOME ACCIDENTS

NATIONAL HEALTH SURVEY, 1935-36

or (in the case of owner-occupied dwellings) estimated value. For the rented dwellings, distinction is made between multiple (i.e., apartments, flats, etc.) and single types (see Figure 4).

In each of the three groups, it is clear that as the rental or value of the house goes down, the rate of home accidents goes up. On the average it may be felt that the lower the rental or value, the more dilapidated the dwelling is likely to be, the darker the rooms, the greater the accident and fire hazard. The chart thus suggests that there is a greater accident hazard due to poor housing.

I recognize that these comparisons miss many fundamentals of the housing problem in its relation to health. We have no measures of the development of neuroses or inferiority complexes. The public health nurse will tell you of the difficulties of giving adequate care in substandard homes—equally true with

respect to medical care in general, always a serious problem in low income families. Vast sociological questions untouched in the data I have presented impinge on health. The diminished opportunities of persons living in slums mean in part diminished opportunities for positive health. Furthermore, statistics are abstract and fail to depict clearly the tragic situation with respect to individual families. But perhaps enough has been said to point the way.

Despite the impossibility of assessing the precise effect of housing conditions *per se*, it seems to me that the National Health Survey data, as briefly summarized here, have established an important broad association between housing and health. Illness rates were found to be higher in congested households, especially for certain diagnoses; digestive diseases were substantially more frequent in households not having private

inside flush toilets; serious home accidents rose with drop in rental or value. What has been demonstrated most clearly is that this excess illness rate, in whatever degree it is to be ascribed to bad housing itself, occurs in the low-income, poorly housed populations who are least able to meet the burden of disease. For it is manifest that at the heart of the housing problem lies the economic problem. A large proportion of the population of this country are not receiving incomes adequate to insure a suitable standard of living. Housing is only one symptom of this maladjustment. It must be attacked as a symptom, but not without realizing that the underlying issue is that of securing a better distribution of income and greater security against the disastrous effects of depressions. Even in this critical period, the safeguarding and furthering of sound social values are important—perhaps more important than ever—both in the extension of health programs to the entire population and in the improvement of housing conditions.

2. A previous article (Perrott, G. St. J., Tibbitts, C., and Britten, R. H. The National Health Survey: Scope and Method of the Nation-wide Canvass of

Sickness in Relation to Its Social and Economic Setting, *Pub. Health Rep.*, 54:1663-1687, 1939) has already described the scope, method, and purpose of the National Health Survey, a project conducted by the U. S. Public Health Service during the winter of 1935-1936, in which some 2,500,000 persons in 700,000 households were covered by the house-to-house canvass method. (The National Health Survey also covered about 140,000 persons in 37,000 households in 23 rural areas.) The total urban surveyed population was so distributed as to give a sample which was, in general, representative of cities in the United States according to size and region. In large cities (100,000 population and over) the population to be canvassed was determined by a random selection of many small districts based on those used in the U. S. Census of 1930. In the smaller cities selected for study, the population was enumerated completely.

The Health Survey schedule is reproduced in the article just cited. The article also contains explanations of many of the terms employed in the present report, of which only the most pertinent will be repeated.

For data classified by city, see Adequacy of Urban Housing in the United States as Measured by Degree of Crowding and Type of Sanitary Facilities. THE PROCUREMENT AND ASSIGNMENT SERVICE

AFFAIRS relating to war efforts are moving so fast and shifting so rapidly that it is difficult for one to keep up with them, and workers in public health, particularly those in the more remote places, find themselves not only confused but at a loss to know what they should do to render their best services in the national interest. Many of them have filled out questionnaires of one sort or another; some have even attempted to follow the activities of the various voluntary committees which arose in the somewhat desultory and leisurely defense period. If up to this time the average public health worker has gained a clear picture of medical preparedness efforts, he will have done more, seemingly, than those who are in the midst of things. Most of the professional organizations related to medicine and public health have carried on surveys to determine existing personnel in their respective fields and have, as it were, offered their services to the federal government. Behind these offers, of course, has been always a deep sincerity and a true patriotism, tinged perhaps sometimes with a forehanded recognition of the desirability of obtaining a place in the sun. As one would expect, this method of procedure has not brought about a hard-driving, tight organization which is capable of moving definitely, swiftly, and authoritatively. Instead there has been confusion approaching chaos. There has been lack of authority on the one hand and duplication of endeavor on the other, and inevitably there has been some maneuvering for position, with subtle and even overt demands for recognition and representation by a few of the various interests and volunteers concerned.

Apparently the federal government, finding itself with this plethora of well meaning but voluntary committees, has decided that the whole problem of recruiting and allocating personnel from the medical and related fields can be solved only by an official governmental agency. To this end, the President, on October 30, 1941, appointed a Procurement and Assignment Service for all physicians, dentists, and veterinarians of the country. This service was organized with a central board, the latter being buttressed with subsidiary committees representing medical education, hospitals, public health, women physicians, information, industrial health and medicine, dentists, veterinary medicine, and Negro health.

The board is placed under the Office of Defense Health and Welfare Services. Its basic functions are as follows: to receive from various governmental and other agencies requests for medical, dental, and veterinary personnel; to secure and maintain lists of professional personnel available, showing detailed qualifications of such personnel; and to utilize all suitable means to stimulate voluntary enrollment, having due regard for the overall public health needs of the nation, including those of governmental agencies and civilian institutions.

The organization of this board with its subsidiary committees does not mean, of course, that voluntary committees will be excluded from participation in this connection. On the contrary, their services will be utilized more than ever, but where before there was distressing dissipation and duplication of voluntary effort, the resources of these agencies will now be focused and directed by one centralized and authoritative governmental agency. The American Medical Association has set an excellent example by providing in the *Journal of the American Medical Association* a blank which any physician may utilize for enrollment with the Procurement and Assignment Service. It is understood that the dental and veterinary associations, through the inclusion of a similar blank in their respective journals, will likewise reach these professions.

One of the most serious problems that this new agency will face is that many physicians, being quite human, would rather apply directly to the Army or Navy Medical Corps for commissions than to volunteer in the Procurement and Assignment Service, which might or might not assign them in the military service and which after all is a civilian agency. In other words, they will want to go into the Army or Navy and will be loath to leave the decision to someone else. From the broad standpoint of national interest, these physicians would be wrong, but unfortunately in times of danger individuals are inclined to take dramatic and emotionally satisfying rather than logical action. Such a procedure would tend seriously to impair the board's purpose of enrolling the total medical service of the country and of allocating it in a manner which will most nearly meet the total needs of the nation in this connection. Because of this problem, the government might in the future find it necessary to follow in this instance the method planned whereby ordinary enlistments in the military and naval forces will be discontinued, with all subsequent recruitments made through Selective Service Boards. If such a step were taken then all applications for commission in the Army and Navy Medical Corps would first be referred to the Procurement and Assignment Service, and commissions would be issued only after clearance with that Service.

THE HONORARY DOCTORATE OF PUBLIC HEALTH

IF one excludes those in the field of education, there is perhaps no professional group so nearly degree mad as are those in public health. This urge to attain better things is, of course, commendable provided the student holds the degree in proper perspective and strives for education rather than for an accumulation of credits. But even such an attitude on the part of candidates would not completely settle this matter, for in many instances the universities are themselves to blame. They, on their part, have set up such a great number of degrees in public health and have so intricately and diversely and gaudily painted these academic totem poles that one is at a loss to know whether or not sound material and good crafts-

manship went into their construction, or whether to compare one with another by length, circumference, weight, design, color, or gloss.

It is difficult to clear up this confused situation. More is involved than mere agreement between the various deans and directors of public health schools, for no small proportion of these degrees are given by universities which, properly speaking, have no public health faculties. Aside from this, the decision as to whether an institution will offer a degree of Master of Public Health or Master of Science in Public Health is not entirely within the hands of the public health faculty when there is one. Decisions of this sort, quite properly, must be made by university trustees, and, to put it mildly, university trustees as a group are not easily moved. Each such board is more concerned with having its degrees fit into its own degree pattern than with giving, in each special field, exactly the same degree as that awarded by some other university.

For these reasons we must continue, perhaps for some years, to have many kinds of Doctors of Public Health and of Engineering and of Science and of Philosophy; and Masters, and Diplomates of various sorts, in public health work. One definite contribution to clarification of this issue was, however, made when the Committee on Professional Education of the American Public Health Association and the Governing Council went on record as deprecating the practice of awarding the honorary Doctor of Public Health degree. The action of this committee was followed by a similar resolution on the part of the Association of Public Health Schools. The particular factors which influenced these bodies in adopting such a resolution are that a Doctorate of Public Health is generally recognized as the highest obtainable degree for academic work in this field; that one possessing this degree is regarded as having pursued, with unusual credit, the basic university courses required and has in addition acquired outstanding competence in some special phase of public health; and that in these circumstances the utilization of this degree as an honorary one tends to detract from the true worth of the earned degree and makes it less significant.

As things have stood in the past, an individual endowed with an honorary Doctor of Public Health was privileged to erect his totem pole with the best of them. The fact that his might be hollow and others solid made no difference to the casual observer. Doubtless, in many instances those on whom this degree was honorarily bestowed were quite worthy of the honor: men seasoned by years of experience in public health work and of proven accomplishment. In an unfortunately large number of other cases, however, recipients have not been outstanding in the field to which the degree relates. Thus, too frequently, one notes Dr.P.H. after the name of a good internist, a sound gynecologist, or some favorite son of a medical school, or learns from the brass plate on the portrait of one who was once in the upper brackets of then current medical politics that the gentleman in question was also a doctor of public health; or wonders if a former dean's reluctant resignation was not furthered by this honorary degree, and suspects that on more than one occasion commencement speakers were paid with a doctorate in public health in lieu of travel expenses.

It is to be hoped that in the future those universities which have been awarding this degree as an honorary one will find it possible to recognize meritorious service or the amenities of the moment in some other way.

D. B. ARMSTRONG, M.D., AND JOHN LENTZ, M.S.

THAT ANNUAL REPORT .

What kind of an annual report should we prepare? This live and generally perplexing question always crops up at this time every year. It is a question that deserves our best thought, for effective annual reports can most assuredly "win friends and influence people." Yet, distinguished annual reports are few and far between in the health field—due perhaps to the fact that too many of us consider them necessary evils, rather than statements which may create confidence in and respect for an agency's work.

What is an annual report? Perhaps it might be wise for all concerned to think about this question before attempting to write an account of the past year's activities. An annual report, we would say, is a statement which, with clarity and sincerity, interprets an organization's program, its policies, its background, its plans, its financial position, and its potentialities so as to gain the sympathetic support of an informed public.

Some time ago a public relations agency classified annual reports under three major headings: (1) The Poker Face Type, (2) The Beautiful, but Dumb Type, and (3) The Man-to-Man Type. The first, or Poker Face type, contains little else but a financial statement with perhaps scanty references to the organization's work. The second, or Beautiful, but Dumb type, is

"dressed up" with fine paper, excellent typography, and striking illustrations—but sets forth little information. The third, or Man-to-Man type, is written and illustrated to conform to the thinking of average people. It leaves readers with very definite ideas about an organization and creates appreciation for the organization's services.

The agency referred to above also found through a survey that many annual reports are difficult to understand. The most popular kind of report was found to be the narrative type which presents a detailed story of an agency's work and progress.

Here are a few "tips" to remember as your 1941 report matures:

1. Decide which group or groups in your community are most interested in the work of your agency and fashion your report accordingly.

2. Do not try to tell "everything" that was done during the year. Stress your major accomplishments. Routine work can be reflected in brief resumés or statistical tabulations.

3. Don't be too "long winded." People like reports that are quickly grasped.

4. Use as many illustrations as possible: photographs, diagrams, charts, pictographs, insignia, maps, reproductions of letters, portraits, and the like.

Let's have more "Man-to-Man" annual reports from health departments and related agencies this year!

THE PLAY'S THE THING

There has been marked improvement in programs which health educators arrange for the public. Not long ago

Please address samples of printed matter, comments, or other editorial contributions to the editors at One Madison Avenue, New York, N. Y.

the typical health meeting consisted of a lecture and the distribution of literature. This type of meeting soon lost its appeal and the motion picture was introduced to bolster attendance. There is now a trend toward presenting brief health plays at these meetings and when well done, they "go over with a bang"—as the theater manager would put it.

Many health meetings are now devoted to the subject of nutrition. This is a topic on which interesting and instructive lectures can be based. It is also a subject around which several good motion pictures have been developed. Now there is a play available on the subject which should be a welcome addition to any nutrition program for the general public. The play is entitled "The Angry Men" and its authors are Norman L. Burnette and Ella Monckton.

"The Angry Men" dramatizes the story of "four deaths, grim as the Horsemen of the Apocalypse: scurvy at sea, beriberi in the Orient, pellagra in the cotton fields, and rickets in the nursery." It tells how these four deaths were conquered by men of science—Eijkman, Funk, Goldberger, and others—through the discovery of vitamins. The play is presented in four intensely interesting episodes, giving the historical background of our present knowledge of vitamins. The dialogue throughout is expertly written.

Copies of "The Angry Men" are available without cost from the authors at 180 Wellington Street, Ottawa, Canada. The authors recommend that the play be used as a "curtain raiser" at nutrition meetings and that a film and a lecture be included on the program also. Complete stage directions and other production details are given by the writers in order that amateur groups may present a finished performance. A cast of twelve is required to enact the various rôles. If facilities for

staging the play are not available, the dialogue might be read by someone skilled in dramatic interpretations.

T.V.A. VS. MALARIA

The Health and Safety Section of the Tennessee Valley Authority has made a number of notable contributions to the science of malariology. The Authority's medical, entomological, and engineering studies in this field are rightly hailed as outstanding public health achievements. Integrated with the Authority's scientific studies, is an intensive health education program. Three excellent bulletins, designed for community groups and schools, have recently been issued by the T.V.A. to implement its educational campaign against this disease.

"Malaria—The Story of an Individual Problem and a Community Problem" is the title of one of the Authority's bulletins. It is a splendid example of the art of interpreting highly technical facts so as to make them intelligible on the third grade vocabulary level. The bulletin, however, does not "put over" its story by words alone. Every page of the publication carries one or more well chosen photographs to illustrate each major point set forth in the text. Of unusual interest are the pictures showing various phases in the life cycle of the mosquito. The basic facts about malaria have never been more successfully and attractively set forth than in this bulletin.

Two other bulletins which the Authority is utilizing in its program for malaria control are addressed to teachers, students, and civic leaders. Basic information on the disease and suggestions for community-wide educational programs are stressed in these publications. Communities making use of these handbooks will find that they are excellent "blue prints" for action against the *Anopheles* mosquito.

From the Authority also comes a

mimeographed report entitled "Malaria in Our Community." This tells of a project in which school administrators, teachers, students and health authorities coördinated their efforts in a malaria control program. The rôle which education plays in the prevention of disease is convincingly demonstrated in this report.

Inquiries concerning these publications (which we hope many health educators will read) should be addressed to the Health and Safety Section, Tennessee Valley Authority, Chattanooga, Tenn.

HAVE YOU SEEN . . .

The Story of the National Foundation for Infantile Paralysis?

In this booklet the Foundation "introduces itself" to the public. In question and answer form, information about the Foundation, its work and the disease it is pledged to fight is set forth. The publication gives a very clear and comprehensive picture of the scope of the Foundation's program. Other noteworthy features of the booklet include an introductory statement by the President of the United States and a foreword by Basil O'Connor, head of the Foundation, in which an appeal is made to every American to help stop infantile paralysis in "its mysterious march of distortion." The Foundation is to be commended on the appearance and content of its publications. They are invariably neat in format and are well written. Copies of "The Story of the National Foundation for Infantile Paralysis" may be had by writing to the Foundation at 120 Broadway, New York, N. Y.

Hidden Hungers in a Land of Plenty?

This is a handbook issued by the National Maternal and Child Health Council, 1710 Eye Street, N.W., Washington, D. C., at 25 cents per copy. It is essentially a compilation of eight

nutrition projects designed to help communities adapt themselves to the broad social changes that are taking place today. The suggested projects outline ways and means to bring about the application of the recommendations made at the National Nutrition Conference in May, 1941. The plan of action suggested in each project is excellent. This handbook should be very helpful to all groups engaged in nutrition programs. Mrs. Franklin D. Roosevelt gives the handbook her blessing in a foreword.

Community Committees for Dental Health—and other publications issued by the National Dental Hygiene Association?

This association, through its publications and other educational activities, is attempting to create a definite lay interest in the dental problem. The publication—Community Committees for Dental Health—describes the magnitude of the dental health problem today and offers suggestions for the development of specific community programs to bring about its eventual solution. The Association also has other literature available including two popular leaflets entitled "Without Warning" and "Some Modern Facts about Healthy Teeth." If interested, write to the Association—934 Shoreham Building, Washington, D. C.

Public Health Progress?

This is the title of the annual report of the Public Health Federation of Cincinnati, Ohio. It is a simple 4 page folder in which the past year's activities are briefly explained—so briefly, in fact, that the cover page carries this notation: "Reading Time—Five Minutes." In view of the anticipated paper shortage, annual reports fashioned along the lines of this one might well take the place of more elaborate reports for the duration.

100 Years of Medicine in Minnesota?

The Minnesota State Medical Association has published a pictorial document under this title commemorating a century of medical progress in that state. The story is an inspiring one and this publication is a fitting tribute to the men and women who pioneered in "frontier medicine." Public health activities in the state are given due recognition in the pages of this publication—the activity of nurses, laboratory workers, and vital statisticians being singled out for especial comment. Inquiries concerning this impressive publication should be sent to the Minnesota State Medical Association, 493 Lowry Medical Arts Building, St. Paul, Minn.

E.D.C. CAMPAIGN

The printed materials produced by the National Tuberculosis Association each year for the Early Diagnosis Campaigns have always been outstanding examples of health publicity. The 1942 materials, however, surpass those issued in other years. The posters, leaflets, and manuals for the 1942 drive certainly reflect credit on the very able staff that planned them. All these publicity items are admirable from an educational point of view. Moreover, they are attractively executed. That a great deal of inspiration and imagination went into the production of these materials is clearly evident.

This year's E.D.C. has three objectives as regards tuberculosis: Find It—Treat It—Conquer It. Three posters, one of which is for display in localities populated by Negroes, stress these objectives so forcefully that "Find It—Treat It—Conquer It" will be remembered by many wherever the posters are displayed. A 32 page manual for volunteer workers is also included among the new E.D.C. materials. This includes organization charts, publicity pointers, and many other features which will be immensely helpful in the con-

duct of the campaign. There are also three new leaflets for this year's drive—one on case finding called "Element'ry, My Dear Holmes," one on treatment with the title "If It Happened to You," and one on the community program and the work of tuberculosis associations entitled "Puzzles Are Easy—If One Knows the Answers."

Since successful campaigns depend largely upon publicity materials, the 1942 Early Diagnosis Campaign should set a record for accomplishment. This annual drive is worthy of the support of all interested in public health.

MAGAZINE ARTICLES

Current popular magazine articles on health or of medical import:

"What to Give a Hospital Patient." Julia DeBarry. *Good Housekeeping*, January, 1942

"A Good Look at Psychoanalysis." Maxine Davis. *Good Housekeeping*, January, 1942

"X-Ray Marks the Spot." Margaret Barnett. *Coronet Magazine*, January, 1942

"Catching Cold—Which Kind?" Greta Palmer. *Cosmopolitan*, February, 1942

"Can They Have Children? (The Rising Problem of Sterility and Infertility)." Albert Horlings. *Harper's Magazine*, January, 1942

"Your Appendix." Louise Fox Connell. *You Magazine*, January, 1942

(The above is not presented as a complete list and the articles cited are not necessarily recommended.)

HOW TO "KEEP POSTED"

The torch of scientific research today burns high. As a result, a constant stream of discoveries—particularly in medical science and public health—issues from educational and research centers at a bewildering rate. Do you not have difficulty, for instance, in keeping up-to-date on the latest vitamins or

the latest sulfa drugs? Certainly many of us do. It is almost impossible to keep track of scientific advances unless one has an unlimited amount of time to read a host of scientific journals—or unless one has steady access to such a publication as *Science News Letter*. Health educators who have not utilized *Science News Letter* as a medium for keeping abreast of current scientific progress should look over a few copies of this weekly magazine. Then and there it would no doubt become the number one publication on your professional reading list.

Science News Letter is published by Science Service, an independent non-profit agency that “feels and reports the pulse of science day by day.” Its writers interpret original research and report other happenings of scientific import in a concise and easily read manner. The articles in this publication are based on authoritative data, thus assuring readers of only the most trustworthy information.

See a copy of this publication and decide for yourself as to its usefulness. Subscription rates may be had by writing to Science Service, 1719 N. Street, N. W., Washington, D. C.

AN EDITORIALETTE:

HEALTH EDUCATION—THE ENZYME

While health education is one of many elements in the public health picture, it is different in character from any of these elements. It is not *just* “one other thing” in preventive medicine. It is or should be an ingredient in all of the basic services in preventive medicine. All other services should be shot through with it or illuminated by it. It is actually or potentially inherent in all of them. It might perhaps be called the enzyme in the process. In the digestive process are involved the mucous membrane of the gastrointestinal tract, the cells of the villi of the intestinal walls, the blood vessels, the

cells of the blood stream, the musculature, and the constituents of the food itself. These all have to be there and all have to do their part. They constitute the basic essentials. But their efficiency and thoroughness are stimulated and released by the effect of the digestive enzyme upon them. Now, in public health, within the school walls, for instance, health education bears a similar relationship to the doctor, the nurse, the clinic, the laboratory, and the other personnel and equipment. Perhaps the analogy has flaws—doctors are apt to do some good in just examining and treating children, with little or no health educational motive, while digestion won't take place at all without the enzyme. Nevertheless in schools, in health centers and clinics, in industry, and in all phases of the public health program, it is the enzyme “health education” that implements and activates its associate forces in the coöperative effort to prevent disease, promote health, and build the vigor and endurance demanded by the stress of living in our time.

(EDITORIAL NOTE: Won't you help us continue this series of “editorialesques?” There must be many subjects in the field of health education upon which you would like to express an opinion. Let us have your thoughts on any of these subjects. You may praise, criticize, or philosophize—provided it is done in not more than a hundred words. While we cannot guarantee publication, serious consideration will be given to your contributions.)

JOTTINGS

Here's another slogan for health workers and everyone else to remember throughout this period of strife and struggle: “Keep Your Chin Off Your Chest!” . . . The story of the discovery of ether is now being filmed in Hollywood. The picture, of feature length, will be called “Triumph Over

Pain." . . . The *New Yorker Magazine* relays the story of a woman in Harrisburg, Pa., who was found to have been sticking anti-tuberculosis Christmas seals on her chest for years as a precaution against the disease. . . . Sidelight on an adversary, as reported in the *New York Times*: "A serious problem of Japanese man power is inherent in the high percentage of soldiers infected with venereal disease. Among the old China hands in Shanghai there is a grim joke to the effect that syphilis has disabled more Japanese than have Chinese bullets. It is claimed that Japanese medical officers can no longer cope with the situation. Syphilis is said to have incapacitated the equivalent of several Japanese divisions." . . . The patriotic motif is now used on many types of health publicity. Here are some important points to remember in this connection: (1) Always

show The Flag pointing to its own right—never show it pointing to its own left, (2) Never show The Flag draped or festooned, (3) Never print The Flag on the face of envelopes where the cancelling of stamps might mutilate it, (4) In using the national colors, the correct sequence is: blue first, white second, red third . . . Line from a Broadway play: "As soon as he entered the hospital, he took a turn for the nurse." . . . Little wonder that William Henry Welch was such a beloved figure, as he was intensely human. The Welch biography (which we again urge you to read) reveals that two of his "weaknesses" were "hot dogs" and Coney Island's chute-the-chutes. . . . The British Library of Information, 30 Rockefeller Plaza, New York, N. Y., has many interesting publications on health under wartime conditions. These are available without cost. . . .

WANTED: The following issues of the *American Journal of Public Health*—April, 1911; February, 1937; January, 1938; February, 1939; July, 1941; and August, 1941. The American Public Health Association will be glad to pay postage for the *Journals*.

BOOKS AND REPORTS

Strange Malady — By Warren T. Vaughan, M.D. New York: Doubleday Doran, 1941. 255 pp. Price, \$3.00.

Strange Malady, as the title implies, suggests that the reader is about to encounter a discussion of one of the human ailments concerning which little is known. However, after perusing the 255 pages of Dr. Vaughan's book, the layman will undoubtedly come to the conclusion that great progress has been made by scientists, both in Europe and in America, during the past twenty years, toward the solution of these strange allergic manifestations. It is to allergy that Dr. Vaughan has given his appropriate title.

The book is divided into five parts. The history of allergy should be of special interest as Dr. Vaughan has had the opportunity, because of his distinguished father's associations, to meet at first hand in his own youth a number of the early students of this specialty, and to acquire from his father intimate details and anecdotes of the work and habits of these scientific men.

In part two the discussion of allergy and the relation of one manifestation to another is linked together in such a concise style that the reader might assume after all the problem is quite simple, and that the solution of the mystery depends only on a careful study of the patient's environment and the history of events in the progress of the disease. This assumption might be correct in a limited number of the victims; the history is most important. But often the patient still "lives" a miserable existence in spite of most careful investigation; and to this sick individual Dr. Vaughan's title can be aptly applied.

The author touches briefly on the treatment of allergy in part three. He devotes only 14 pages to this phase of

his publication. He must have given careful thought to his final decision to limit this discussion to the barest details. Only confusion would have resulted had he attempted to present the many procedures with which the allergist attempts to relieve his patient.

Part four begins with the statement that "Sensitization to foods is the commonest form of human allergy." The reviewer takes exception to this statement, disagreeing with the opinion of Dr. Vaughan and other members of this school of thought. It is unfortunate that he has placed such emphasis on "food allergy." Many of the conservative allergists will not agree with him as he has no scientific proof to substantiate such a broad generality. Likewise, many trained internists will heap criticism upon his head if they read this book. There are individuals who are specifically sensitive to certain foods, a small minority in the opinion of the reviewer. The statement would have been better and more accurate had he emphasized that often an inexperienced or over-enthusiastic allergist confuses the digestive symptoms of a patient, who is nervous and harassed by financial or domestic problems, for gastrointestinal or "food" allergy. Fortunately in part five the author mentions the possibility of such confusion.

Thus with one exception, and an important one, the book contains many entertaining and instructive characteristics of a fascinating and baffling variety of affections.

Mr. Tillery's illustrations are unique and amusing, but at the same time they portray accurately many of the complicated problems of immunity and they greatly enhance the value of the book to the reader.

LESLIE N. GAY

Housing Yearbook — Coleman Woodbury and Edmond H. Hoben, Editors. Chicago: National Association of Housing Officials, 1941. 399 pp. Price, \$3.00.

Local housing developments during 1940 and early 1941 are rather fully reviewed state-by-state and city-by-city in the principal section of this seventh *Housing Yearbook* of the National Association of Housing Officials, which constitutes the definitive record of recent progress on the fronts of construction, management, and public relations. Each of the federal housing agencies is represented by a summary of its current program, and several new organizations created to deal with emergency needs for defense housing facilities have contributed reports on their purposes and early accomplishments.

In addition to the usual directory of official and unofficial housing agencies, the volume contains a special report on the organization, research programs, legislative activities, budgets and methods of financing, etc., of 19 of the leading local housing associations. This analytical study sheds valuable light on the methods by which effective voluntary housing organizations can best be developed, and should be helpful to all those who have occasion to work with citizen housing groups in their own communities. ALLAN A. TWICHELL

Nutrition in Everyday Practice—*A Compilation from the Canadian Medical Association Journal*—1938–1939. Evansville: Mead Johnson, 1939. 94 pp. Paper. Free.

This excellent little volume is a compilation of "eighteen authoritative articles on normal nutrition which appeared regularly during 1938 and 1939 in the *Canadian Medical Association Journal*." These articles as chapters, each by a different author, are of the length of a 15 minute radio talk, which several of them actually were. They adequately

cover the subject of nutrition from a practical standpoint and should be admirably suited for instructing the physician or public health officer in "Nutrition in Everyday Practice." That this volume would not be suitable for a textbook in nutrition in no way detracts from its usefulness for the purpose stated in its title. Chapter subjects include: calories, protein, fat, pregnancy, lactation, childhood, calcium, bread, iron, iodine, canned foods, resistance to disease, and several general discussions of nutrition and feeding.

The importance of a nutrition improvement program for every public health administrator is being increasingly recognized. If lack of knowledge of the science of nutrition holds some back, a good practical guide, such as this little volume is, will be helpful and stimulating. A paper covered edition has been printed and is being distributed by Mead Johnson and Company.

D. F. MILAM

The Public Health Nurse in Action—By Marguerite Wales. New York: Macmillan, 1941. 437 pp. Price, \$2.75.

Here is a book that was needed, for it makes interesting reading of what public health nurses do in the city and in the country. Nursing procedures have been omitted, but there are ample references to standard manuals and texts for those who want that kind of information. Both layman and professional health worker will find this book informative. It should prove helpful to college students seeking literature for vocational guidance, and particularly to the nurse student who has yet to choose her field of nursing. I hope also that board members and health officers will read this book, for it will make them proud of their public health nurses.

The foreword by Lillian D. Wald, founder of the Henry Street Visiting Nurse Service, sets the scope and tone of the book which is sustained through-

out its ten chapters. The author presents some of the principal fields in which nurses are engaged and also those diseases which constitute the greatest menace to public health, such as tuberculosis, syphilis, gonorrhea, and chronic illness. Each chapter begins with a brief statement of the health problems in this particular field as they affect the community and the nation, followed by illustrations of what they mean to individuals and their families and what the public health nurse does to help them help themselves. Some of the characters in the case stories will linger in the reader's memory, as little Dolores Acosta, a plucky child with a bad heart, and her determined mother, do in mine.

In the last chapter, Miss Wales reaffirms her belief in the importance of the work of the public health nurse. She speaks of her as "a galvanizing agent. Hers is the responsibility of keeping plans alive and seeing that they are carried out." I believe that everyone who reads this book will agree with the author.

EMILIE G. SARGENT

Nutritional Deficiencies—By John B. Youmans, M.D., assisted by E. White Patton, M.D. Philadelphia: Lippincott, 1941. 385 pp. Price, \$5.00.

This book, primarily intended for practitioners of medicine, is apt to be invaluable to all physicians and particularly to teachers of medicine and nursing. The subject matter deals with human deficiency disease rather than data obtained from animal experimentation and empirically applied to the human subject. Ill health resulting from inadequate intake or utilization of protein and essential minerals receives equal consideration to that given to the avitaminoses.

The inadequacy of present knowledge of human deficiency diseases is emphasized, and always the author's attitude is conservative. The problems of human nutritional disease are clearly stated and

the various conditioning factors defined. Protective, preventive, and curative therapy are differentiated and accurately outlined.

The chemistry and biochemical significance of the known vitamins are presented as adequately as present knowledge of their functions can be translated into clinical terminology. The same is true of the discussion of protein and the essential minerals. There is an excellent tabular summary of the vitamins and an equally good guide to the important food sources of the essential nutritive factors.

The final section describing the best current laboratory methods for diagnosis of nutritional deficiencies will be of great importance to all physicians with access to good clinical laboratory facilities as well as those interested in nutritional research. No better presentation of the laboratory diagnosis of deficiency disease has appeared.

The book can be recommended as an accurate and authoritative source of information for all who are interested in the clinical and biochemical problems of nutritional disease.

V. P. SYDENSTRICKER

Hippocratic Medicine, Its Spirit and Method — By William Arthur Heidel. New York: Columbia University Press, 1941. 149 pp. Price, \$2.00.

The small book *Hippocratic Medicine* by the late Professor William Arthur Heidel is one to be owned, to be kept handy on one's bookshelf, to be read several times and to be consulted frequently. It is a work suited to serve for the tyro as an introduction to Hippocratic medicine, and for the more mature student as a reference work, an epitome, and a digest of medical thought and science during the Periclean Age.

The tyro will do well to pass over the parts beyond his grasp, while the better versed will find the whole work stimu-

lating and instructive. The book is not difficult to read, or to understand. Its author, however, was a master in his field and he plays upon themes and personalities with the ease and flash of a virtuoso.

This, too, is a timely work. Modern medicine has reached the stage of synthesis, where its many heretofore isolated parts fall into a harmonious rational pattern. *Hippocratic Medicine* will aid us to grasp the transcending significance of this experience. It will sharpen our wits to appreciate the new—ancient medical problems, those of nutrition, of the total man and his environment, of the interrelationship between macrocosm and microcosm, problems of utmost importance to the public health worker and the physician.

To the Josiah Macy, Jr. Foundation, which by a grant to the author, made the composition possible, and to the Columbia University Press, which published it, medicine and public health are indebted for a significant and valuable contribution to the cultural wealth of The Art.

IAGO GALDSTON

Lymphatics, Lymph, and Lymphoid Tissue—Their Physiological and Clinical Significance—*By Cecil Kent Drinker and Joseph Mendel Yoffey. Boston: Harvard University Press, 1941. 406 pp. Price, \$4.00.*

This volume is Number Two of the Harvard University Monograph series in Medicine and Public Health.

The book is divided into two major parts: Dr. Drinker, the senior author, has written the first five chapters, which pertain largely to the anatomical and physiological features of the lymphatic system. He discusses the permeability of blood capillaries, the permeability of lymphatics, lymph flow and lymph pressure, and the chemical composition and physical characteristics of lymph.

Dr. A. Baird Hastings, Professor of Biological Chemistry at Harvard Medi-

cal School, has collaborated in chapter 5, on the electrolytes of lymph.

The junior author, Dr. Yoffey, is interested in the lymphoid tissue primarily, as contrasted with the functions of the lymph and its movement, and has contributed chapters 6, 7, and 8, on the biological significance of lymphoid tissue, the cell content of lymph, and the lymphocyte. The final chapter, by Dr. Drinker, deals with the practical considerations that may be related to the matters previously discussed in the monograph.

This comprehensive and extraordinarily fine monograph is a brief summary of the years of strenuous and fruitful work that have been devoted to the study of a relatively unexplored field. It is an authoritative text, which should be on the shelves of every medical library. The bibliography is comprehensive and an important asset to the text.

W. G. SMILLIE

Occupational Diseases—*By Ruth-erford T. Johnstone, M.D. Philadelphia: Saunders, 1941. 524 pp., 132 ill. and 26 tables. Price, \$7.50.*

The question of workmen's compensation does not usually enter into the relationship between a physician and his patients, even though many of them are working people. However, with an employed group of 52,000,000 people, many cases will arise which pertain to employment—and in some of them the question of responsibility will be uncertain. The adequate handling of such cases demands that the physician know and understand the obligations placed upon medical practice by workmen's compensation. This book will show him how to do this. It excellently describes these obligations and gives instructions how to comply with them. It will be of great value to both the industrial physician and the general practitioner and is definitely an important contribution to industrial medicine.

Part I discusses the functions and administration of workmen's compensation, including methods of evaluating disability.

Parts II to VIII consider the occupational diseases incident to skin irritants, the use of toxic materials, dusts, environmental conditions, etc. Their sources, prevention, diagnosis, treatment, and medicolegal aspects are discussed.

Part V concerns the handling of two of the most troublesome problems of industrial medicine and compensation—the "industrial back" and hernia.

Part VIII relates the medicolegal relationships of trauma to disease and to the neuroses; while the last chapter deals with the preemployment examination.

This book will do much to aid the general practitioner as well as the specialist in the field of industrial medicine. Its publication is very opportune during this period of national emergency when the importance of the health of the defense workers is recognized and the general practitioner's opportunities in industrial medicine are steadily increasing.

C. D. SELBY

Prepayment Plans for Medical Care—*By Franz Goldmann, M.D. New York: Joint Committee of the Twentieth Century Fund and the Good Will Fund; and Medical Administration Service, Inc., 1790 Broadway, 1941. 60 pp. Price, \$.25.*

This small but very substantial pamphlet first discusses the general principles of voluntary prepayment of medical care and then gives a comparative study of 5 plans of organized medical care for self-supporting people. All 5 use group practice to furnish medical service, and all use clinics of their own as the basis of their activities. They differ in so far as 2 are organized as consumers' coöperatives, 2 are connected with group clinics oper-

ated by private physicians, and 1 is under the management of an industrial corporation. The main purpose of the study was to find out how complete the scope of the services offered was and, second, how much the medical care furnished actually cost.

It is impossible to go into detail, but the pamphlet can be recommended most warmly. Goldmann has carried out his study carefully and critically, and the facts and figures he gives will be found most useful. Medical service plans of varying types have been operated in this country in the last ten years in increasing numbers. Much valuable experience has been gained, and I wish Dr. Goldmann would analyze, summarize, and criticize it in a book that would include all these plans. Such a comprehensive study would be of greatest value when the country gets ready for its Second National Health Program.

HENRY E. SIGERIST

L. Baxter, *Medicus* —*By Knud Stouman. New York: The Greystone Press, 1941. 406 pp. Price, \$2.75.*

Knud Stouman is well known to many workers in public health for his statistical studies with the League of Nations and the League of Red Cross Societies, and for his admirable report (co-author with I. S. Falk) on "Health indices. A study of objective indices of health in relation to environment and sanitation" (*Quarterly Bulletin, Health Organisation, League of Nations*, 5:901, 1936).

In "*L. Baxter, Medicus*," Mr. Stouman has written a leisurely and charming novel of the late 17th century, working up toward the end to crises of vivid dramatic interest. The hero is a medical apprentice in New York, a medical student in Holland and England, and a practitioner again in New York. He and his associates are vital personalities painted against a historical background that is always pic-

turesque and accurate, but never obtrusive. Both Leeuwenhoek and Sydenham appear in person in the course of the narrative. Public health workers will be particularly interested in the historically plausible demonstration of variolation and in the account of the first official American autopsy actually performed by Kerbfile in 1691 under the conditions described in the novel as applying to Dr. Baxter.

C.-E. A. WINSLOW

Administrative Medicine—*Edited by Haven Emerson, M.D. New York: Nelson, 1941. 839 pp. Price \$7.50.*

The fields of public health and of medical care have now so far overlapped that it is timely and interesting to find them both treated in a single volume and under a new name. Dr. Emerson has called on as many as fifty-six authors to discuss the various phases of work in these related fields and presents their contributions, with an introduction of his own, in a sizeable volume bound in loose-leaf form.

Designed primarily for the medical practitioner, specifically in the words of the editor, "to correct a common tendency among physicians to concern themselves only with the medical and health needs of their own patients," the usefulness of the book is by no means limited to this class. It may tend also to correct a common tendency of health workers to concern themselves only with their own peculiar problems.

To the health worker the section on public health will attract first attention. It is in fact a series of essays on the various phases of public health organization and administration. These essays contain a wealth of information, much of which is not elsewhere available. The individual contributions are for the most part of high quality, although, as is inevitable in multiple authorship, there is some repetition and some lack of unity and balance. In

spite of these minor defects, however, the public health worker will find this part of great interest and value.

The discussion of the organized care of the sick is somewhat unusual. Hospitals and their allied services are treated fully and effectively and there are excellent chapters on visiting nursing, on sickness surveys, on home medical care, on the medical service of the military forces and on university health services. Only in the final two chapters of the book is attention given to the most important of all pending questions in administrative medicine, the organization of medical service for those able to pay all or part of its cost.

The final chapter, entitled "The Economic and Social Basis of Administrative Medicine," makes clear that medicine can never make its full contribution to society until existing economic barriers to the extension of medical service are removed. It is on this note, surprisingly enough, that the book closes.

The book is a real contribution to the all too scant literature of the subject and will be welcomed by all workers in public health and its allied fields. To the many contributors and to the editor are due the thanks of us all.

A. W. FREEMAN

An X-ray Atlas of Silicosis—By Arthur J. Amor, M.D. (Lond.), M.Sc. (Wales). Baltimore: Williams & Wilkins, 1941. 206 pp. Price, \$8.00.

This is an altogether admirable book and great credit is due to the author and his collaborators. The material is presented in a clear, brief, and succinct manner that tells the story without the wastage of a word. The chapter on the etiology of silicosis embodies not only a great deal of experience but emphasizes the different conditions that exist in various types of industry, without an appreciation of which the clinical picture of silicosis must always be confusing. The main body of the book is

devoted to reproductions of x-ray films of the chest. These reproductions are very well done and are accompanied by a full account of the working and clinical history of each individual. Some of the films are in series. Various stages of silicosis are shown with and without infection. The film reproductions also illustrate the appearances that are seen in different types of industry and it is the demonstration of this, together with the pertinent data, that gives this book its particular value. There is an interesting foreword by Sir Wilson Jameson.

A. J. LANZA

Play for Convalescent Children in Hospitals and at Home—By *Anne Marie Smith*. New York: Barnes, 1941. 133 pp. Price, \$1.60.

A new note in the convalescent care of children is struck in this helpful little volume.

The author recognizes that it is the whole child who is sick and not any one organ or organ system. The processes of repair therefore demand treatment of the total personality. It is estimated that 40 per cent of a child's day in the hospital is occupied by physical care. The problem is to fill up constructively the other 60 per cent.

From a wealth of experience in The Children's Memorial Hospital in Chicago and in other institutions the author has worked out a systematic program of play activities for convalescent children based upon modern principles of child behavior. An excellent chapter on the organization and administration of a "Department of Play" gives the basic requirements. This is followed by a chapter on the practical application of play activities and their uses under varying conditions. Suitable types of play material for children at different age levels are given a place. Children's favorite story books are listed. A unique chapter on the classification of tested forms of play indicates the practical

application under hospital conditions. A well selected bibliography is appended. This book is highly recommended for nurses and hospital social service workers. RICHARD A. BOLT

Obstetrics for Nurses—By *Joseph B. De Lee and Mabel C. Carmon* (12th ed.). Philadelphia: Saunders, 1941. 651 pp. Price, \$3.00.

This new edition of one of the standard texts in obstetrics for nurses is brought up to date by the addition of recent statistics, descriptions of new procedures, and new illustrations. The character of the text is not changed and largely represents the teaching and practices of one institution.

The statement which appears on page 549, "The subject (of pelvimetry) is far too complicated and extensive for full presentation in a nurses' textbook . . .," suggests the philosophy that has influenced the presentation of the subject matter throughout the book. The nurse with a real desire to understand the physiologic processes of maternity in relation to obstetric procedure will find the book inadequate.

HAZEL CORBIN

Encephalitis: A Clinical Study—By *Josephine B. Neal, M.D., Sc.D., F.A.C.P., and Associate Authors*. New York: Grune & Stratton, 1942. 563 pp. Price, \$6.75.

This book surpasses the expectation of the most critical reader. Its title is modest, to say the least, for it has been given to an outstanding work which represents an exhaustive study of epidemic encephalitis by a foremost authority on the subject. The reader will find a wealth of information on each individual type of the large group of known encephalitides; such disease entities as the St. Louis and the Japanese B types, human encephalitis caused by the viruses of eastern and western equine encephalomyelitis, Russian verno-estival

tick-borne encephalitis, the Australian X-disease, lymphocytic choriomeningitis, louping-ill, the Guillain-Barré syndrome, toxoplasmic encephalomyelitis and hemorrhagic encephalitis are discussed in proper perspective. The material is logically arranged and clearly presented by Dr. Neal and her collaborators: Drs. Bender, Harrington, Muckenfuss, Putnam, Rosner, and Stevenson.

The text is well illustrated with 40 figures and tables; there are over 100 selected case histories and over 600 references arranged in sequence at the end of each sub-chapter of the book. The author and her associates present a complete picture of epidemic encephalitis in all its aspects: epidemiology; clinical course in acute, intermediate, and chronic phases of the disease, supplemented by discussion of the symptomatology, laboratory aids, differential diagnosis, prognosis, and causes of death. Therapy is fully discussed and augmented by the author's extensive clinical experience. Surgical treatment of post-encephalitic symptoms is given due consideration. Chapters on psychiatric sequelae; post-encephalitic behavior dis-

orders of childhood and on pathology give much valuable information that would otherwise require hours of search in medical libraries. It is interesting to note the review of data on neurological complications following acute infections and vaccination as well as the discussion of the pathology in parasitic encephalitis, the encephalopathies and in botulism. The excellent clinical work of the Matheson Commission for Encephalitis Research is cited in the text.

Every public health worker will profit by frequent reference to this volume, which is written in a clear style and reads like an adventure story; the publishers deserve special mention for the fine finished product and selection of the readily legible type. The health officer, the diagnostician, the epidemiologist, as well as the laboratory and follow-up workers, will find in this book a ready reference volume which will greatly aid them in gaining a more complete understanding of the many different forms of encephalitis. This book truly fulfils a need that has long existed in medicine and in public health.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Something New Is Added—British miscellany. . . . Health activities of the League of Nations are being carried on from Geneva and Singapore. . . . Shelter life and general war conditions have not had a deleterious effect on health as feared. . . . It is illegal (in England) to manufacture or sell any food substitute unless licensed. . . . As rose "hips" and hawthorn berries are 6 times as rich in vitamin C as oranges, a tea of rose hips is recommended. . . . Germinated grain is a good available source of vitamins and has been widely used in India. . . . Tuberculosis in young English women 15 to 25 appears to be increasing.

ANON. Editorial Notes. *J. Roy. Inst. Pub. Health & Hyg.* 4, 11:254 (Nov.), 1941.

Sister Kenny Deserves a Big Hand—Having subjected the Kenny method of treating infantile paralysis to comparative studies, a committee of the National Foundation concludes that the method reduces the time of pain and spasm and the incidence of contractures and produces better end results than other methods of treatment. The committee urges health officers to be ready for the early diagnosis of poliomyelitis and to arrange for the application of the new methods. Personnel must be trained and this is another health administrative job. Just in case you haven't heard, the Kenny method abandons splinting and adopts continuous hydrotherapy and physical therapy to maintain function and increase comfort.

ANON. The Kenny Method of Treatment in the Acute Peripheral Manifestations of Infantile Paralysis. *J.A.M.A.* 117, 25:2171 (Dec. 20), 1941.

Married Folks Really Live Longer—It is hard to believe that the favorable mortality from tuberculosis, accidents, suicide, alcoholism, and syphilis among the married does not arise as a benefit from normal family life, even though selection is operative (marriage tends to exclude the unfit). So concludes this interesting statistical study.

ANON. Why Married People Live Longer. *Stat. Bull.* 22, 11:4 (Nov.), 1941.

"The Time Has Come . . ."—To put health education, and health educators, in its place and their proper places. This is the high aim of a fine, forthright discussion, which was heard by too few of us at the Atlantic City meeting.

ARMSTRONG, D. B. Health Education—An Appraisal. *J.A.M.A.* 117, 24:2060 (Dec. 13), 1941.

Finding TB Outside the Great Cities—Is the clinic investigating a reasonable percentage of reported cases? Is the clinic program economically justified? Has there been an increasing percentage of early cases found? Has it been profitable to examine contacts? Does the project stimulate public interest? These are all valid questions: their answer when applied to one non-metropolitan area is the basis of an excellent paper.

BLISS, T. L. Tuberculosis Case Finding. *J.A.M.A.* 117, 23:1944 (Dec. 6), 1941.

Speaking of School Health Examinations—Although we have a means of knowing which children in a community will grow up into physically handicapped adulthood, we have so far done precious little about it. As we are now

reaping the whirlwind of our neglect (in our selectees) this would seem to be a fitting time to do something about bettering our methods.

Ciocco, A., *et al.* Child Health and the Selective Service Physical Standards. Pub. Health Rep. 56, 50:2365 (Dec. 12), 1941.

Big Encephalitis Outbreak—News Item—If you feel that your knowledge of the increasingly more menacing encephalitides is a little shaky, then this brief but inclusive review will bring you up to date. The bibliography of 186 references will prove a valued addition to your working papers. There are three methods of attack with which you should be on speaking terms: extermination of the hosts, extermination of vectors, and immunization of the (human) victims.

DINGLE, J. H. The Encephalitides of Virus Etiology. New Eng. J. Med. 225, 26:1014 (Dec. 25), 1941.

"With Eyes to See"—Are water- and food-borne outbreaks of disease worth reporting and epidemiologic study? One state reports half of all the country's water-borne outbreaks, but this state has top notch sanitary services and supervision. Three states report over half the milk-borne outbreaks. No reports come from some states where sanitary conditions are deplorable.

FUCHS, A. W. Disease Outbreaks from Water, Milk and Other Foods in 1939. Pub. Health Rep. 56, 48:2277 (Nov. 28), 1941.

Introducing Met and Clo—It is suggested that these newly named units of thermal activity and insulation be used by physiologists, physicians, and heating engineers, instead of the variety of complicated terms each employs to the confusion of the others. For your information, a met is a measure of thermal activity roughly the equivalent of that of a 100 watt lamp, and a clo

has about the insulation value of your old heavy topcoat.

GAGGE, A. P., *et al.* A Practical System of Units for the Description of the Heat Exchange of Man with His Environment. Science 94, 2445:428 (Nov. 7), 1941.

Neglected Children—Among Chicago school children the extensive need for health supervision was made manifest by an examination of a large sample. At no family income level is the health generally satisfactory, but at the low levels it is definitely unsatisfactory—as one might anticipate.

HARDY, M. C., *et al.* Physical Fitness of Children from Different Economic Levels in Chicago. J.A.M.A. 117, 25:2154 (Dec. 20), 1941.

Behavior of the "Bombed" Child—Well, this is no longer merely an academic question! Air raids do affect the child though the prognosis is good (judging by this report of limited British experience) in those cases not complicated by existing neurotic trends.

MONS, W. E. R. Air Raids and the Child. Brit. M. J. 4217:625 (Nov. 1), 1941.

Authoritatively Yet Simply Told—What is known about thiamin, riboflavin, pyridoxin, nicotinic and pantothenic acid is told in as few and as non-technical words as is possible for so difficult a subject. Yeast, wheat germ, liver, eggs, milk, greens, and legumes furnish these chemical constituents of the vitamin B complex.

MORGAN, A. F. The B Vitamins. Pub. Health Nurs. 33, 12:711 (Dec.), 1941.

Why Should State Health Services Be in the Health Department?

—Tuberculosis control is carried on by a dozen different classifications of agency in as many different states: some have as many as five official departments for this one activity alone. The astounding variety of miscellaneous state agencies that have acquired responsibility for

food and drug control (ranging from slaughterhouses to beauty parlors), the multiplicity of state divisions having to do with crippled children, and the haphazard growth of all the other categories of public health administration call for clarification. This is masterly understatement.

MOUNTIN, J. W. A Plea for Unity in Health Administration at the State Level. *J.A.M.A.* 117, 23:1958 (Dec. 6), 1941.

Alcohol and Steering Wheels—“Bleary Eyed” is a widely popular phrase to denote one stage of intoxication. Evidently it is quite accurately descriptive as well. The visual acuity of fifty drivers was tested before and after imbibing what might be termed a snoot-full of whisky. Where a concentration of 115 mg. of alcohol per 100 ml. of blood was achieved, significant

deterioration of visual acuity occurred; but there were great variations in potential driving ability among the testees.

NEWMAN, H., and FLETCHER, E. The Effect of Alcohol on Vision. *Am. J. Med. Sci.* 202, 5:723 (Nov.), 1941.

Understanding Human Behavior—I suggest that you cross out the word “nursing” from the title of this excellent paper, then read it in the light of whatever your particular job may be. Paraphrasing the closing sentences: your aim is to grow in the understanding of people—their needs and ways of expressing them—so that you may comprehend their attitudes about health, and be instrumental in directing them toward that goal.

ROBERTS, D. I. Mental Hygiene in Public Health Nursing. *Pub. Health Nurs.* 33, 12: 719 (Dec.), 1941.

CORRECTION

IN listing public health degrees and certificates granted in the United States and Canada during the academic year 1940–1941 in the December *Journal*, page 1308, through a regrettable error the number of graduate students enrolled in public health courses at the Harvard School of Public Health was given as 51 instead of 75. The number of graduates receiving the Master of Public Health degree from Harvard was listed as 6. The number should have been 34. This changes the totals of Table 3 on page 1309 to:

Number of students registered—658; and number of graduates receiving each degree and certificate—332.

This would also change Table 4 on page 1310 as follows:

Number of graduates receiving the Master of Public Health degree—155; total number of graduates receiving degrees and certificates—332.

This also changes the summary at the end of Table 4 on page 1310 to read as follows: “In the academic year 1939–1940, 550 graduate students were enrolled as compared with 658 in the academic year 1940–1941. Graduate degrees and certificates granted in the academic year 1939–1940 totalled 331 as compared to 332 in the year 1940–1941.”

Reprints of the report with the correct figures are available on request.

ASSOCIATION NEWS

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Theodore P. Day, M.D., 1905 Prospect Place, Knoxville, Tenn., Assistant Health Officer and Epidemiologist, Bureau of Health
Earl N. Mathis, M.D., 440-A Ninth Ave., San Francisco, Calif., Venereal Disease Control Officer, State Health Dept.
P. A. Steele, M.D., Superintendent of Health, Decatur, Ill., Dept. of Public Health and Safety
Claude A. Thomas, M.D., District 3, Health Office, Point Pleasant, W. Va., Director

Spencer, W. Va., Sanitarian, State Health Dept.
Lawrence R. Tabor, B.S., in C.E., P. O. Box 148, Thomasville, Ga., Public Health Engineer, Thomas County Health Dept.
Winston B. Taylor, B.S., 209 Raleigh, Oxford, N. C., Trainee for Sanitation, School of Public Health, Univ. of North Carolina
Thomas H. Wall, M.S., 1404 Raymond Ave., St. Paul, Minn., Asst. Public Health Engineer, State Dept. of Health

Laboratory Section

Elizabeth Conroy, B.S., State Laboratory, Powers, Mich., Junior Bacteriologist, State Dept. of Health
Edward V. Lipscomb, M.S., State Board of Health, Jacksonville, Fla., Junior Bacteriologist
Joseph A. McCarthy, Lawrence Experiment Station, Lawrence, Mass., Chief of Laboratory, Dept. of Public Health
Alice Lee Quan, M.S., 1800 Cassatt Ave., Jacksonville, Fla., Bacteriologist, State Board of Health
Virginia Reid, B.S., 520 N. 10th St., Klamath Falls, Ore., Laboratory Technician, Klamath County Health Dept.
Ralph L. Tracy, Ph.D., California Institute of Technology, Pasadena, Calif., Research Bacteriologist
Joel Wahlin, Ph.D., Univ. of Arkansas, School of Medicine, Little Rock, Ark., Professor of Bacteriology
Dorothy B. Wells, A.B., 124 S. 36th St., Philadelphia, Pa., Asst. Instructor in Bacteriology, Dept. of Public Health, School of Medicine, University of Pennsylvania
Gertrude P. Willmert, M.S., Univ. Campus, Minnesota Dept. of Health, Minneapolis, Minn., Bacteriologist

Vital Statistics Section

Hannah S. Rifkind, A.B., U. S. Children's Bureau, Washington, D. C., Asst. Statistician

Engineering Section

George W. Gehres, B.S., 304 High St.,

Industrial Hygiene Section

Pauline E. Kuchler, Standard Oil Co., Whiting, Ind., Industrial Nurse
Zena M. Raleigh, R.N., First St., Ingleside, Tex., Industrial Nurse, Humble Oil & Refining Co.
Roland Rooks, Ph.D., 266-A Medical Lab. Bldg., Univ. of Iowa, Iowa City, Ia., Asst. Professor of Hygiene and Preventive Medicine
Charlotte Silverman, M.D., 615 N. Wolfe St., Baltimore, Md., Student, Johns Hopkins School of Hygiene and Public Health

Maternal and Child Health Section

Lena M. English, M.D., Mercer Cottage Hospital, Mercer, Pa.
Rudolf L. Roddy, M.D., Noble Hill, Abington, Pa., Asst. Physician, Bureau of Maternal and Child Health, State Dept. of Health

Public Health Education Section

Richard A. Aszling, A.B., 1005 Hartman Theater Bldg., Columbus, Ohio, Director, Bureau of Public Education, Ohio State Medical Assn.
Marie Fortunati, M.Ed., 22 Glenville Ave., Allston, Boston, Mass., Health Educator, Boston Health Dept.
Mildred Frier, B.S. in Ed., 3858 Westminster, St. Louis, Mo., Home Economist Consultant, Family Welfare Agencies

NEW MEMBERS OF THE COMMITTEE ON ADMINISTRATIVE PRACTICE

THE Executive Board of the Association on the nomination by Dr. Henry F. Vaughan of Ann Arbor, Mich., Chairman of the Committee on Administrative Practice, has reappointed Dr. Haven Emerson of New York and H. A. Whitaker of Minneapolis, Minn., for 4 year terms. It also appointed Dr. George H.

Ramsey, Commissioner of Health for Westchester County Department of Health, White Plains, N. Y., for a 4 year term and appointed George B. Darling, Dr.P.H., of Battle Creek, Mich., to complete the unexpired term caused by the death of W. Frank Walker, Dr.P.H., New York, N. Y.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearing house on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

UNASSEMBLED EXAMINATIONS IN WEST VIRGINIA

The Merit System Council of West Virginia, Box 873, Morgantown, has announced that it is expected that unassembled examinations will shortly be given for the following positions in the West Virginia State Health Department.

<i>Position</i>	<i>Salary per month</i>
Chief of Medical Services.....	\$325-\$400
Ophthalmologist	275- 350
Director of County Health Work.....	350- 400
Director, Maternal & Child Hygiene.....	350- 400
Director, Communicable Diseases	350- 400
Director, Vital Statistics	350- 400
Director, Industrial Hygiene.....	350- 400
Assistant Director, Maternal & Child Hygiene.....	320- 375
Assistant Director, Communicable Diseases (Venereal).....	320- 375
Assistant Director, Tuberculosis.....	320- 375
Venereal Disease Consultant.....	320- 375
Senior Health Officer.....	320- 375
Junior Health Officer.....	280- 320
Health Officer Trainee.....	\$200

Residence in West Virginia has been waived in consideration of the applications for these positions. However, residents of the state may be given preference in making appointments. Complete information may be obtained by writing to the Merit System Council.

U. S. CIVIL SERVICE COMMISSION

The Commission has announced that applications will be received for positions as Senior Medical Officer (\$4,600), Medical Officer (\$3,800), and Associate Medical Officer (\$3,200) for appointments in the Public Health Service, with the Food and Drug Administration, Veterans' Administration, and the Indian Service. Forms for application may be obtained from the U. S. Civil Service Commission, Washington.

Junior Public Health Nurse. A civil service examination for Public Health Nurse (\$2,000) has been open for some time. Nurses who have been unable to qualify for this examination because of the experience requirement now have an opportunity to qualify through a new Junior Public Health Nurse examination (\$1,800) which requires no experience. Applications are also being received for examinations now open for Junior Graduate Nurse (\$1,620) and Graduate Nurse for general staff duty (\$1,800). Further information and application forms may be obtained at any first or second class post office or from the Civil Service Commission, Washington.

POSITIONS AVAILABLE

Young woman, trained in Home Economics, for group contact work in behalf of an important commercial organization whose products are useful in the protection of public health and the National Nutrition Program. Experience in the public health field or related fields is essential. Office in New York, some

travel involved. Write Box H, Employment Service, A.P.H.A.

Southern State Department of Health seeks physicians qualified by training and experience as County Health Officers or as Pediatricians. Write Box B, Employment Service, A.P.H.A.

Western State Department of Health

will consider applications from physicians with experience and a degree in public health. Write Box S, Employment Service, A.P.H.A.

County Public Health Nurses for New Mexico. Must have four months' post-graduate instruction under one of the recognized public health nursing courses and one year's experience. Must drive and have a car. Address inquiry to State Health Department, Santa Fe, N. M.

Physician with either public health training or experience in local health department administration to serve as health director in a county health department in mid-western state. Salary \$4,000 and \$500 travel (flat rate). Well established department with offices in attractive little city of 10,000. Write Box T, Employment Service, A.P.H.A.

Laboratory Director—Bacteriologist—\$2,400. For combined hospital and health department laboratory with staff of 10 and visiting pathologist in charge of hospital aspects. Bacteriological experience and training especially desired. Opportunities for expanding program good. Reply Box G, A.P.H.A. Employment Service.

Wanted: Trained Public Health Nurse, starting salary \$1,500 per year and traveling expense, increase to \$1,700 within 6 months. Saginaw County Health Department, Saginaw, Mich.

The State Department of Social Security and Welfare, Crippled Children's Division, of Phoenix, Ariz., has three vacancies to be filled. Examinations will soon be held for orthopedic nursing consultant, nurse-physical therapist, and medical social worker.

Further information may be obtained by writing to the Merit System Supervisor, Room 208, 128 North First Avenue, Phoenix, Arizona.

PHYSICIANS WANTED IN CINCINNATI

Carl A. Wilzbach, M.D., Commissioner of Health of Cincinnati, has announced that there are vacancies for white male physicians, aged 23 to 50, graduates of recognized colleges of medicine, licensed to practise in Ohio, for appointment to

the Cincinnati Health Department. Duties include surveillance over communicable disease, infant and child welfare work, medical service for sick poor, epidemiological surveys of communicable disease, examinations for work certificates, school teachers, etc., vaccination, medical school inspection. Salary \$2,640 to \$3,360 plus transportation allowance of \$240 per annum. Eligible for a retirement system. Persons interested should communicate with Dr. Wilzbach, Commissioner of Health, City Hall, Cincinnati, Ohio.

PUBLIC HEALTH ENGINEER

Responsible professional public health engineering involving field investigations and office studies in the application of sanitary measures. The more difficult engineering and sanitation field surveys include supervision over public water supplies, sewerage systems and sewage treatment plants and review of plans for same, and promotion and supervision of sanitation programs. Minimum qualifications: Training and experience equivalent to 3 years' civil engineering experience, including 2 years in public health or sanitary engineering; or completion of an academic year of graduate study and a year's experience in sanitary or public health engineering; and graduation from a college of recognized standing with a major course in civil or sanitary engineering. The salary range is \$205 to \$250 per month depending upon experience. Apply Box E, Employment Service, A.P.H.A.

Southwestern State Health Department seeks 2 physicians for assignment to district health units, to personally conduct several small venereal disease clinics on a rotating schedule. Experience preferred but not required. Salary \$3,000, plus actual travel allowance not to exceed \$1,200. Write Box V, Employment Service, A.P.H.A.

Middle western city, 125,000 population, seeks well trained and experienced Health Officer on full-time, with competence to administer a department and teach public health to medical students. Salary \$5,000 to \$5,500 per annum. Write Box K, Employment Service, A.P.H.A.

POSITIONS WANTED

ADMINISTRATIVE

Physician, M.D. Tulane, M.P.H. Johns Hopkins, age 31, experienced as health unit director, prefers administrative position in the South. A-488

Physician, age 32, 5 years clinical and administrative experience in venereal diseases, wishes administrative position in venereal disease control, preferably at state level. A-490

HEALTH EDUCATION

Teacher and research worker, man, Ph.D., age 52. Extensive record as college professor of biology and hygiene and investigator, for the past two years engaged in research. H-499

Health Educator, Negro, man with background of High School administration and M.S.P.H. from University of Michigan, seeks position in Health Education. Public agency or educational field. Excellent references. H-497

Woman, M.S. in public health, excellent graduate training in education, 8 years' experience as business executive (sales and publicity). Just completed year's research in community education. Seeks good administrative position. H-496

Health Educator, M.A. in Education, 10 years' background in community organization for public health education, also teaching of personal and community health at high school and college levels. Public health nurse, able to teach mental and social hygiene as well as general health education. East preferred. H-498

Health Educator. Man with M.S. in preventive medicine and public health. Negro. Seeks position in Health Education or field work with official or non-official agency. H-500

Woman with master's degree in health education, 12 years' successful experience in public school and college teaching, administration and research. Will consider position in normal school, public schools,

or in official or nonofficial health agencies. Prefers South or East. Available at once. H-501

LABORATORY

Milk Sanitarian and Technologist, age 37, Ph.D. Bacteriology, Wisconsin, 10 years' experience in milk and food sanitation from industrial and official angle, seeks administrative position with opportunity for research or investigational work preferred. L-381

Chemist, Sc.D., Biochemistry, Johns Hopkins University. Age 31. Public health laboratory experience, teaching experience. Desires position with promise of advancement, preferably in commercial organization. L-461

SANITARY ENGINEERING

Public Health Engineer, M.S. Harvard, experienced in public health and industrial hygiene, wishes position of better sort in public health engineering or industrial hygiene. E-470

Public Health Engineer, M.S. Harvard, with more than 10 years' experience including 5 years with state division of sanitation, is available. E-468

STATISTICAL

Woman with academic, business and research experience in vital statistics, seeks a position in the vital statistics division of a state or city health department, preferably as registrar. S-459

Experienced and well trained public health nurse, with background of tuberculosis, venereal disease, school, industrial, and generalized services, will shortly be available for appointment. Three years as director of state nursing service. Experienced as university teacher of public health nursing. M.A., New York University. M-449

PUBLIC HEALTH PHYSICIANS WANTED—

(a) City physician; state capital; \$300; South. (b) District health physician for rural community; \$250-\$325; public health training not required. (c) Epidemiologist for appointment in large eastern city; physician with experience as medical administrator in health department preferred; \$3,800-\$4,800. (d) Staff appointment with social hygienic clinic; physician with some general training in public health required; around \$3,300; Midwest. (e) Commissioner of maternal and child health; public health or obstetrical experience required; \$4,320. (f) Physician with teaching experience, ability as organizer and public speaker, for unusual appointment; considerable travel involved. (g) Venereal disease clinician; responsibility will include supervision of several small venereal disease clinics; annual income (including travel allowance) around \$4,200; Southwest. (h) Assistant health commissioner; city health department; around \$2,700; Ohio. (i) Physician with minimum year's training in obstetrics for special training course in public health obstetrics; some credit will be given toward American Board; \$150, plus travel allowance. (j) Woman physician with outstanding ability as public speaker for appointment as lecturer in state-wide cancer control program; \$200, generous expense allowance; car furnished. PH2-1, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

PUBLIC HEALTH NURSES—(a) Advisory nurse for department of maternal and child health; around \$195, plus travel allowance; degree, public health certificate, postgraduate work obstetrics or

pediatrics required. (b) Educational director; mid-western state health department; teaching background and supervisory experience, plus public health certificate required; \$2,400. (c) Educational director for field training center, state health department; degree, public health certificate required; South. (d) Public health nurse with minimum year's experience for county health appointment; \$140-\$150, travel allowance; Far West. PH2-3, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

SANITARIANS—(a) Sanitary engineer; county health department; about \$2,500, including travelling expenses; Midwest. (b) Chief sanitarian; district health department serving population of 5,000; degree, postgraduate work in public health required; 3-5 years' field experience desirable; \$2,400, plus travel allowance. PH2-4, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

BACTERIOLOGIST—Preferably one with M.D. or Ph.D. degree; department of pathology and bacteriology, university medical school; both teaching and hospital experience essential. PH2-5, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

NUTRITIONAL CHEMIST—Department of biochemistry, university medical school; training or experience beyond Bachelor's degree required; transfer later to board of health laboratory. PH2-6, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

Situations Wanted

Advertisement

PUBLIC HEALTH PHYSICIAN—B.S., M.D. degrees, eastern schools; C.P.H., Johns Hopkins; 4 years, health commissioner, midwestern city of 60,000; 3 years, head department of health and physical education, state university; 4 years, assistant commissioner, state health department. PH2-7, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

PUBLIC HEALTH NURSE—B.S. and Diploma in Nursing, M.S. in Social Administration, Western Reserve University; several years' experience as instructor; 8 years, supervisor, public health unit

consisting of five counties. PH2-8, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

BACTERIOLOGIST—B.S., M.D., D.Sc. degrees, with majors in bacteriology; certificate in public health, eastern university; several years' teaching experience, including professorship in bacteriology and pathology; able lecturer; now interested in public health appointment. PH2-9, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

NEWS FROM THE FIELD

TOLAN COMMITTEE HEARING ON PUBLIC HEALTH

A HEARING before the Tolan Committee of the House of Representatives (Select Committee Investigating National Defense Migration) was held in Washington on January 15. The panel of persons engaged in public health who were invited to appear included Reginald M. Atwater, M.D., Executive Secretary, American Public Health Association, New York, N. Y. (Moderator); Martha M. Eliot, M.D., Associate Chief, Children's Bureau, Washington, D. C.; Alma Haupt, R.N., Nursing Consultant, Health and Medical Committee, Federal Security Agency, Washington, D. C.; George H. Ramsey, M.D., Commissioner of Health, Westchester County, N. Y.; James G. Townsend, M.D., Director Industrial Hygiene Division, National Institute of Health, Washington, D. C.; Huntington Williams, M.D., Commissioner of Health, Baltimore; Abel Wolman, Dr.Eng., Professor of Sanitary Engineering, Johns Hopkins University, Baltimore.

In presenting the panel, Dr. Atwater quoted a high British official who recently had said that the greatly expanded social and health services in England did as much to win the Battle of Britain as the Royal Air Force. British experience shows that many people fear loss of security in health and economics even more than they fear death by bombing. The English people know that, no matter what happens to their homes as a result of air raids, they need not worry about their economic or health security. They are enabled to rebuild their homes through insurance provisions, they are able to feed, clothe, and shelter their families through the social services and give

them medical and health services as well. What is lost is lost by all; what is saved is saved for the use of all. On such a foundation morale is built.

The focus of this hearing relates to the part which health security can play in building and maintaining this morale in the present emergency. The members of this panel, representing as they do a variety of public health specialties, have a simple message for this committee on which they are entirely agreed.

1. We know what good health services are and we can supply a blueprint.
2. Even a perfect blueprint left on paper will not meet the need. It is necessary to implement this blueprint in order to build public morale.

In summary, the panel presented the following information:

Health Services in War Time

Health officers and health department staffs are expected always to be on duty to fulfil urgent needs of civil government. Our present state of war calls for a clarification of aims, some simplification of organization, and a considerable strengthening of effort to develop and keep fit a nation of superior men, women, and children capable of an optimum life within the privileges and duties of free peoples.

The public health profession is already on record as to what should be the minimum functions and the organization principles for health activities. For the sake of the record there was submitted a statement of these principles unanimously adopted by the American Public Health Association at a recent meeting. (See *A.P.H.A. 1940-1941 Year Book*, pp. 43-50.)

Wherever these minimum functions now exist we believe that service must be maintained during the emergency. Wherever they do not exist we point out that our nation is vulnerable at that point and we believe these services must be established.

In order to build public morale it must be emphasized that in every area of the United States and its territorial possessions these functions need extension and improvement. We believe that it is vital here and now to translate those principles into militant action. These blueprints must be converted into practical programs for state, city, and county work, and the voluntary organizations must take an appropriate place with the official agencies.

The public health profession has a single aim and that is victory for the United Nations, and to this end we as a body of public servants dedicate all the resources of our professional and technical capacities.

Any neglect or curtailment of the essential protection of civilian health, whether at home or in the factory or other work place, is inconsistent with maximum efficiency of the military forces and the preservation of public morale.

We believe that the trained civil health worker is properly to be considered indispensable to the maintenance of national health. We believe that he should be encouraged to continue at his regular station in civil government unless it is clear that the war can be more effectively prosecuted by his transfer to military service.

In order to build sound public morale, those states and more limited areas now wholly or in large measure lacking the reality and in some instances even the form of responsible health services by trained and experienced health officers devoting their entire time to the public need, and to enforcing the reasonable and necessary provisions

of sanitary and public health law, should be with all speed provided with health officers competent to give leadership and direction, and authorized to spend public funds sufficient to make health services a reality for every unit of population and for every area of civil jurisdiction under the flag of the United States.

It should be recognized that a competent modern health department comprises a medical, sanitary and related biological and social service which enjoys broad authority to meet a wide variety of emergencies.

We believe that at present it is neither politically desirable nor legally practical to create a fully centralized health authority under the federal government. We believe, however, that ways must be found to help the health officer and each member of his staff to think of himself as conducting an essential portion of a national project for the people's health and as acting at all times as if he were in fact at the administrative disposition of the Surgeon General of the U. S. Public Health Service. We are glad to see that steps are being taken to expand the reserve of the Public Health Service, even though those who are commissioned may be expected to remain in their key positions unless their presence elsewhere is urgently demanded through enemy action or through the presence of epidemic disease.

We believe that, if the public will accept and act with vision and confidence upon the principles and policies here declared, victory in arms can be achieved without sacrifice of the continuing and progressive health needs of a people devoted to the humanities of peace.

This introduction was followed by specific testimony as to the means by which the technics of public health can be used to build public confidence and morale. Dr. Martha Eliot spoke of the

opportunity to use maternal and child health services. Miss Alma Haupt spoke on the use of public health nursing and other nursing services. Dr. George H. Ramsey and Dr. Huntington Williams spoke from the standpoint of local health officers. Dr. James G. Townsend spoke from the standpoint of industrial health and the contribution which can be made through the employment by factories of adequate staffs for the health protection of their personnel.

At the conclusion of this hearing the Right Honorable Malcolm Macdonald, High Commissioner for the British Empire to the Dominion of Canada, Ottawa, testified as to the usefulness of public health services in Great Britain during the present emergency. He emphasized the wide variety of responsibilities which were thrown upon health personnel and indicated how some health jurisdictions had undergone a change in their programs so that much more than half of the time was devoted to emergency services rather than to the conventional side of public health.

Complete testimony will become available with the report of the Tolan Committee, of which Representative John H. Tolan of California is Chairman.

DR. L. R. THOMPSON APPOINTED CHIEF
INSPECTING OFFICER, U. S. PUBLIC
HEALTH SERVICE

DR. LEWIS R. THOMPSON, Director of the National Institute of Health and Assistant Surgeon General in charge of Scientific Research, has been appointed Chief Inspecting Officer of the U. S. Public Health Service, a new position established in the Office of the Surgeon General.

In announcing Dr. Thompson's appointment, Surgeon General Thomas Parran stated that the personnel and activities of the Public Health Service have been greatly augmented during the past year to meet the demands of mili-

tary and civilian defense. As a result, it is important to consolidate, under one head, the field activities of the district offices of the Public Health Service and of its liaison officers in the army corps areas. In order to undertake these additional duties, Dr. Thompson is relinquishing his post at the Institute at his own request.

Dr. Thompson, who is a native of Indiana, was born in 1883, received his medical degree at Louisville Medical College in 1905, and entered the Public Health Service in 1910. During much of his career he was closely associated with the late Dr. Wade Hampton Frost in epidemiological studies. As a part of his duty Dr. Thompson has served in the Philippine Islands; he was the first Chief of the newly established office of Industrial Hygiene Investigation in 1921, and since 1930 has been Assistant Surgeon General in charge of the Division of Scientific Research.

While in charge of this division the separate offices of cancer research, child hygiene, goiter investigation, industrial hygiene, malaria investigations, milk investigations, nutritional research, sewage disposal, stream pollution, undulant fever, and statistical studies have come under his supervision, as well as the National Institute of Health. During his administration the National Institute of Health was reorganized into eight divisions and there has been initiated a federally supported cancer research program and the National Cancer Institute. The Division of Chemotherapy was added to the Institute in 1940. During this period also the headquarters of the Institute were transferred to a group of new buildings at Bethesda, Md.

DR. ROLLO E. DYER APPOINTED DIRECTOR
OF NATIONAL INSTITUTE OF HEALTH

EFFECTIVE February 1, 1942, as announced by Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, Dr. Rollo E. Dyer,

Assistant Director of the Institute, has been appointed Assistant Surgeon General in charge of the Division of Scientific Research of the Public Health Service and as Director of the National Institute of Health, succeeding Dr. Lewis R. Thompson who has been appointed Chief Inspecting Officer of the U. S. Public Health Service.

Dr. Dyer, who is a native of Ohio, was born in 1886. He is a graduate in medicine from the University of Texas in 1915 and, following his internship, he was commissioned in the Public Health Service.

Since 1921 Dr. Dyer has been detailed to the National Institute of Health (formerly the Hygienic Laboratory) and he has been closely identified with the late Dr. Joseph Goldberger and Dr. George W. McCoy. Since 1937 he has been Chief of the Division of Infectious Diseases at the Institute. In addition to studies on streptococcal infections, especially scarlet fever, he has made contributions to the knowledge of the rickettsial infections, notably typhus fever. He first identified the virus of typhus fever in rat fleas taken from houses where cases of endemic typhus were occurring, thus demonstrating that the body louse is not the only insect vector of typhus infection.

for the development of a broad program of public health training.

The difficulties which the Institute faces in financing and developing public health work do not apply in the development of biophysics, biochemistry, and biotechnology. This work is already expanding under the leadership of Dr. Francis O. Schmitt with the help of a \$200,000 grant from the Rockefeller Foundation and a special grant of \$70,000 from the same source to set up an electron microscope center. Beginning next July this program and the work in food technology will be administered as a Department of Biology and Biological Engineering.

The present program in public health and public health engineering will continue for 2 years as a separate Department of Public Health, but only such undergraduate and graduate students will be admitted as may reasonably be expected to qualify for a degree within that period. Subsequently the Institute will offer public health subjects only in public health engineering, in food technology, and as electives. Dr. Clair E. Turner, who retires as Professor Emeritus in 1944 after thirty years of service at M. I. T., has been appointed to head the separate Department of Public Health, beginning July 1.

CHANGES IN PUBLIC HEALTH COURSES AT MASSACHUSETTS INSTITUTE OF TECHNOLOGY

THE Massachusetts Institute of Technology has announced a change in its program of professional training in public health to become effective June 30, 1944. After that time the public health program will be restricted to the training of public health engineers and food technologists. This change recognizes the increased importance of the medical and social sciences in the training of many types of public health workers, which makes the university better adapted than a technical school

UNIVERSITY OF MINNESOTA FELLOWSHIPS 1942-1943

THE University of Minnesota has announced a number of in-service fellowships in Public Administration for the academic year 1942-1943. The period of training for in-service fellows will extend through the fall, winter, and spring quarters and for the first term of the summer session. Individual courses of study will be planned for each student, depending upon previous preparation, personal interests, and the requirements of public service. These in-service fellowships will carry stipends varying in amount from \$1,000

to \$1,500 a year, depending upon the student's experience, his present salary, and the number of his dependents.

Applicants for these fellowships must be citizens of the United States, not over 35 years of age, graduates of recognized universities and colleges, and must qualify for admission to the Graduate School of the University of Minnesota. They must have had not less than 3 years of experience in public service, preferably in a position involving some administrative responsibility. Each applicant must be endorsed by his governmental employer, and he should secure promise of a leave of absence for the duration of his fellowship year.

Applications must be submitted not later than April 1, 1942. Appointments will be announced May 15 or as soon thereafter as possible. Requests for application blanks and for further information should be addressed to the Secretary of the Committee on Training for Public Administration, 13 University Library, University of Minnesota, Minneapolis, Minn.

ADVISORY BOARD ON SANITARY AND PUBLIC HEALTH ENGINEERING

THE Office of Civilian Defense, Washington, D. C., has announced that the members of the National Technological Civil Protection Committee, appointed by the Secretary of War in January, 1941, have agreed to act also as an Advisory Board on Sanitary and Public Health Engineering to the Medical Division of the Office of Civilian Defense. The committee, representative of engineering and related societies, includes:

Walter D. Binger, New York, N. Y., American Society of Civil Engineers, Chairman
W. H. Carrier, Syracuse, N. Y., American Society of Heating and Ventilating Engineers
Frederick G. Frost, New York, N. Y., American Institute of Architects
E. M. Hastings, Richmond, Va., American Railway Engineering Association

Harry E. Jordan, New York, N. Y., American Water Works Association
W. Cullen Morris, New York, N. Y., American Gas Association
John C. Parker, New York, N. Y., American Institute of Electrical Engineers
Arthur B. Ray, New York, N. Y., American Institute of Chemical Engineers
Scott Turner, New York, N. Y., American Institute of Mining and Metallurgical Engineers
James L. Walsh, New York, N. Y., American Society of Mechanical Engineers
Abel Wolman, Baltimore, Md., American Public Health Association

The Office of Civilian Defense will have a contact member on this committee as does the War Department. Ralph E. Tarbett, Senior Sanitary Engineer, U. S. Public Health Service, who has been assigned as Chief Sanitary Engineer of the Medical Division of the Office of Civilian Defense with headquarters in the Washington office, will be the contact member for the Office of Civilian Defense.

Regional Sanitary Engineers are being appointed by the Medical Division of the Office of Civilian Defense to work through state defense councils with state health departments in planning defense against belligerent action. Most important of their immediate duties will be to promote development of protective measures for public water supplies, which may be subject to destructive enemy action. The engineers will also consult with health authorities on such matters as emergency maintenance of sewerage, sanitary facilities, garbage disposal, protection of food and milk supplies in the event of a disaster.

Two regional sanitary engineers are already on duty. Gordon E. McCallum, sanitary engineer, U. S. Public Health Service, has been commissioned in the Public Health Service Reserve and assigned to the Third Civilian Defense Region (Pennsylvania, Maryland, District of Columbia and Virginia) plus West Virginia and Ohio. Mr. McCallum is stationed in Washington.

John H. Brewster, at various times sanitary engineer for the American Waterworks and Electric Company and for the New York and Indiana State Health Departments; and recently a private consultant in Troy, N. Y., has also been appointed a sanitary engineer in the Reserve of the Public Health Service and assigned to the First and Second Regions (New York, New Jersey, Delaware and the New England States).

NEW RADIO HEALTH CAMPAIGN

THE Federal Security Agency, the U. S. Public Health Service, and the U. S. Department of Agriculture are coöperating with the Women's National Emergency Committee and the National Broadcasting Company in presenting the new winter series of "Listen America," the coast to coast radio campaign for better national health, which opened on November 23. Included on the premier program was Dr. William Henry Sebrell, Jr., of the Federal Security Agency, Washington, D. C.

NEW YORK STATE DEPARTMENT OF HEALTH

AMONG recent changes in the staff of the New York State Department of Health are the following:

Thomas D. Dublin, M.D., Dr.P.H., has been appointed Epidemiologist in the Division of Communicable Diseases.

Robert F. Korn, M.D., Dr.P.H., has been transferred from the position of Assistant District Health Officer in the Amsterdam District and has been appointed Epidemiologist in the Division of Communicable Diseases.

The following have been appointed Assistant District Health Officers and are assigned to the Districts indicated:

Theodore S. Drachman, M.D., New York, N. Y.

Earle H. Harris, M.D., M.P.H., Geneva

Berwyn F. Mattison, M.D., Albany office

Terry S. Montague, Gouverneur
Louis Platt, M.D., M.S.P.H., Middletown
Arthur M. Rubin, M.D., Buffalo
Edward R. Schlesinger, M.D., Syracuse

NEW JERSEY HEALTH AND SANITARY ASSOCIATION

THE following officers were elected at the Annual Meeting of the New Jersey Health and Sanitary Association on December 5, 1941:

President: H. F. Kilander, Ph.D., Glen Ridge
First Vice-President: Joseph H. Kler, M.D., New Brunswick

Second Vice-President: M. Warren Cowles, New Milford

Third Vice-President: C. Byron Blaisdell, M.D., Long Branch.

Dr. John L. Rice, who spoke at the annual meeting luncheon, delivered a paper on "Changing Trends in Public Health."

HEALTH IN HOME AND NATIONAL DEFENSE

THE theme of a conference sponsored by the Florida State-wide Public Health Committee in Orlando, Fla., on January 16-17, 1942, was "Health in Home and National Defense."

The guests of honor were: Thomas Parran, M.D., Surgeon General of the U. S. Public Health Service, and Mrs. Spessard L. Holland, wife of the Governor of Florida. There were many speakers from outside the state including: Carl E. Buck, Dr.P.H., and Benjamin G. Horning, M.D., Field Director and Associate Field Director respectively of the American Public Health Association; James A. Crabtree, M.D., Executive Secretary, Health and Medical Committee, Federal Security Agency; John A. Ferrell, M.D., Associate Director, International Health Division, Rockefeller Foundation; Ruth O. Blakeslee, Merit System Consultant, U. S. Children's Bureau; and, Harry E. Handley, M.D., Assistant Director, Division of Public Health, The Commonwealth Fund.

PERSONALS

Central States

JOHN A. CARSWELL, M.D., D.P.H.,[†] who has been employed with the Wisconsin Anti-Tuberculosis Association, Milwaukee, has been appointed Deputy Commissioner and Director of the Division of Maternal and Child Health of the Peoria, Ill., Department of Health, effective February 1. He will be associated there with S. M. MILLER, M.D.,[†] Commissioner of Health, replacing JOSEPH H. KINNAMAN, M.D., M.P.H.,* who has become Health Officer of New Rochelle, N. Y.

HARLEY F. FLANNIGAN, M.D., Lagrange, Ind., has been named Health Commissioner of Lagrange County, succeeding DR. FRANK MORSE NICHOLS, Topeka, resigned.

GEORGE F. FORSTER, M.D.,[†] Assistant Chief of the Division of Laboratories in the Illinois Department of Public Health, Chicago, has been appointed Associate Professor of Bacteriology in Loyola University School of Medicine.

BRUNO GEBHARD, M.D.,* Director of the Cleveland Museum of Health and Hygiene, has been invited by DR. ANGEL DE LA GARZA BRITO, Dean of the School of Public Health and Hygiene, Mexico, to visit Mexico City to confer with local authorities on the establishment of a health museum.

CLIFFORD H. GREVE,[†] Statistician of the Division of Venereal Disease with the Michigan Department of Health, has been granted a leave of absence. He has been called to active duty as a First Lieutenant, Medical Administrative Corps, United States Army, and is stationed at Michigan Selective Service Headquarters, Lansing, Mich. The Governor of Illinois recently appointed the following to the Board of

Public Health Advisers in the State Department of Health: DRS. WALTER D. STEVENSON of Quincy, RAYMOND W. MCNEALY, JAMES H. HUTTON and ROBERT S. BERGHOFF, Chairman, all of Chicago. DR. CLIFFORD U. COLLINS, Peoria, was reappointed to the board, which serves in an advisory capacity to the State Director of Public Health.

Eastern States

PETER F. HARRINGTON, M.D., Providence, R. I., has been appointed Director of a new Division of Tuberculosis Control in the Providence Health Department.

Southern States

MIRIAM E. BRAILEY, M.D.,[†] Associate in Epidemiology, Johns Hopkins University School of Hygiene and Public Health, Baltimore, Md., has been appointed Director of the Bureau of Tuberculosis of the City Health Department.

CHESTER A. HICKS, M.D.,[†] Cochran, Tenn., formerly with the Georgia State Department of Health, has been placed in charge of Carter-Union-Johnson Counties Health Unit, Elizabethton.

CARL A. NAU, M.D.,* formerly Director of the Texas Division of Industrial Hygiene, is now Professor of Physiology and Preventive Medicine and head of the Department, University of Texas School of Medicine, Galveston.

ARDZROONY PACKCHANIAN, M.D.,[†] who has been with the National Institute of Health, U. S. Public Health Service, Washington, D. C., has accepted Associate Professorship in Bacteriology and Tropical Medicine, Department of Preventive Medicine and Public Health, Medical School, University of Texas, Galveston.

DERRIC C. PARMENTER, M.D., Tupelo, Miss., has succeeded DR. THOMAS L.

* Fellow A.P.H.A.
[†] Member A.P.H.A.

HARVEY as Head of the Dyer County Health Department, Dyersburg, Tenn. WILLIAM L. PHILLIPS, M.D., Centerville, Tenn., Director of the Hickman County Health Department, has been named Registrar of Vital Statistics for the County.

RAYMOND H. RUND, M.D., Mount Vernon, Mo., has been named Medical Director and Superintendent of the Peoria, Ill., County Tuberculosis Sanatorium District, with offices in Peoria, succeeding DR. DAVID F. LOEWEN,† Decatur, Ill. Dr. Loewen will occupy a similar position at the Macon County Tuberculosis Sanatorium District.

Western States

THEODORE G. LATHROP, M.D., of White Salmon, Wash., has been appointed Acting Health Officer of Klickitat County.

RAYMOND MEL PERRY, M.D.,† Pasco, Wash., was recently appointed Director of the Sevier County Department of Health, Tenn., succeeding DR. LAMAR A. BYERS, Sevierville, who is studying at Johns Hopkins University.

DEATH

LLOYD HENRY SARCHET, M.D., of Wellington, Kan., City and County Health Officer, died on November 14.

† Member A.P.H.A.

Occurrence and Recovery of the Virus of Infantile Paralysis from Sewage^{*}

JOHN R. PAUL, M.D., AND JAMES D. TRASK, M.D.

*Section of Preventive Medicine, and Department of Pediatrics, Yale University
School of Medicine, New Haven, Conn.*

THE discovery that the virus of poliomyelitis could be found in human feces was made in Sweden about thirty years ago,¹ and corroborated in the United States a few years later,² but interest in these findings soon waned because for a long time no one repeated the discovery. About four years ago, however, this fact, namely the presence of virus in human stools, was "rediscovered," and it soon became evident that in young patients recently convalescent from poliomyelitis it is easier (perhaps much easier) to demonstrate the virus in the stool than in the nose or throat. One reason for this is, that after an attack of the acute disease the virus remains in the intestinal tract for longer periods of time than in the throat. In stools it has been repeatedly found, in the second or third week of convalescence from a severe or mild attack of the disease.³ In one series of cases it was demonstrated in almost 70 per cent of the cases tested.⁴ Occa-

sionally the virus may persist in the stools for months, as was noted in a report from Paris where the virus was isolated from the stool of a child who had sustained a mild attack of the disease 123 days prior to the time when the test was made.⁵

These findings tend, whether rightly or wrongly, to place poliomyelitis in the category of so-called intestinal diseases, which include typhoid fever and dysentery. We are not on the firmest of ground in classifying poliomyelitis this way, for we do not know whether the presence of the virus in the stools of patients is a direct or even an indirect link in the chain which actually leads this agent from one patient to another. But from the epidemiological standpoint, from the engineering standpoint, and from the public health standpoint, the intestinal tract seems like a dangerous place for this virus to be. During epidemics, the dissemination of poliomyelitis virus throughout the community is great, particularly when one considers how much virus may be present in a single human stool (for somewhere between 1,000 and 10,000 doses infective for the monkey have been demon-

^{*} Read before the New Jersey Section of the American Water Works Association and the Engineering Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 16, 1941.

strated in a 50 gm. stool). Most of this dissemination occurs through carriers, which are usually unrecognized. Although in the more severe urban epidemics, the case rate is seldom greater than 1 per 1,000, this usually refers to the paralytic and frank cases. The more common, abortive cases harbor the virus as well if not better than the paralytic cases. They outnumber the paralytic cases by many times⁶ and, as they are generally undiagnosed, they actually are the equivalent of transient healthy carriers. It is readily seen then how great a quantity of virus must enter urban sewers during epidemic times, and it becomes important to know something of the conditions under which it survives in this medium.

Before describing experiences with sewage, however, it is worth mentioning the fact that poliomyelitis virus is quite stable and more resistant to chemicals than certain bacteria such as *Escherichia coli*. This virus survives well in 15 per cent ether and in low dilutions of phenol. In suspensions of human feces it keeps at icebox temperature for months.⁷ In sterile water, preserved in the light at room temperature, the virus has been found active after 31 days⁸ and in the dark for 114 days.⁹ In milk the virus has been found active after 25 days⁸; and at icebox temperatures after 180 days.¹⁰ In butter it has survived at -2°C . as long as 91 days.¹¹

Poliomyelitis virus is killed by the same degree of heat which kills most bacteria, in other words, exposures of 45° to 50°C . for 30 minutes are sufficient to inactivate the virus.¹² Ultra-violet light is also known to be injurious to the virus *in vitro*, exposure for short periods such as 5 seconds may noticeably weaken the virus, and longer exposures inactivate it.¹³

A practical question in this connection is one which concerns the resistance of the virus to chlorine. This has proved to be a difficult problem to

answer, and none of the experiments as yet reported in the literature lend themselves to ready interpretation or practical application. In our own laboratory we have been carrying on experiments with the assistance of the Chemical Division of the Wallace and Tiernan Company of Newark, N. J. We have used suspensions of virus from infected spinal cord (which has been the technic employed by most other workers in this field), and also suspensions of virus as it naturally occurs in the human stool from patients convalescent from the human disease. The work is not completed and the results have been somewhat irregular.

From the literature we find that Levaditi, Kling, and Lépine, in 1931,¹⁴ found that 4 p.p.m. of Cl_2 was capable of rendering artificially contaminated, slightly turbid water non-infectious after 24 hours; while 0.4 p.p.m. was effective in clear preparations. Kempf and Soule, in 1940,¹⁵ reinvestigated this problem employing a 1:1,650 suspension of (M.V.) virus in water to which varying amounts of Cl_2 had been added and found that 0.5 p.p.m., which is in excess of that usually employed in municipal water treatment, did not inactivate the virus of poliomyelitis in $1\frac{1}{2}$ hours, but did so in 4 hours. The same investigators together with Pierce, in 1941,¹⁶ next studied the effect upon the virus of sodium and calcium hypochlorite in tap water which gave a resulting Cl_2 concentration of 1.0 p.p.m. This failed to inactivate poliomyelitis virus after 4 hours' exposure, at the end of which time the Cl_2 , however, had fallen to 0.2 p.p.m. A concentration of 1.5 p.p.m. of Cl_2 in tap water inactivated the virus in 20 minutes and a concentration of 0.55 p.p.m. inactivated it after 1 hour. It may be noted that the latter amount is equivalent or even in excess of that often employed in swimming pools.

So much for laboratory experiments.

The next question concerns the actual circumstances under which the virus of poliomyelitis has been demonstrated in water, or more accurately in sewage. To date there are seven tests in which this has been successfully accomplished in urban or hospital sewage during epidemic times. They include one positive test made in Charleston, S. C.,¹⁷ three from a hospital sewer in Detroit,¹⁷ one from Stockholm, Sweden,¹⁸ and two from New York City.¹⁹ Most of the positive tests have been obtained in the vicinity of hospitals, which is not surprising when one considers how resistant poliomyelitis is, and how much virus poliomyelitis patients may discharge. From the sewage studies it appears that the virus may still be detected when considerable dilution has taken place,¹⁷ and we find that it may be transported by sewage for at least an eighth of a mile,¹⁷ and perhaps for several miles.¹⁹ Such findings raise the question, of course, as to whether or not poliomyelitis virus may not be a normal inhabitant of sewage, like tetanus bacilli or tubercle bacilli, for the mere presence of such organisms in sewage would tell us little about the epidemiology of the human infections which these bacteria cause.

It is desirable to know, therefore,

whether or not poliomyelitis virus may not be present all the time in urban sewage—that is, winter and summer, in good years and bad. If it were present at all times, such a finding would be in keeping with one theory of the pathogenesis of this disease, namely, that we are constantly exposed to the virus, winter and summer, year in year out, and only when profound alterations occur among the local population does the clinical disease come to the surface. To answer this question, a series of 22 tests on 11 post-epidemic sewage samples has been made in four large cities.¹⁷ All of them were negative. We have also made a series of 87 tests on sewage during inter-epidemic periods both in winter and summer.¹⁹ Samples tested represented hospital sewers and main sewers in the City of New Haven; and one of the larger collecting sewers in New York City, namely the Manhattan Grit Chamber indicated in Figure 1. From all these tests which have been carried on monthly for almost two years now, two positive results have thus far been obtained from New York City in September, 1940, and October, 1941. These were not years of large epidemics in New York City but the first positive test was encountered in the local sewer in the month (September, 1940)

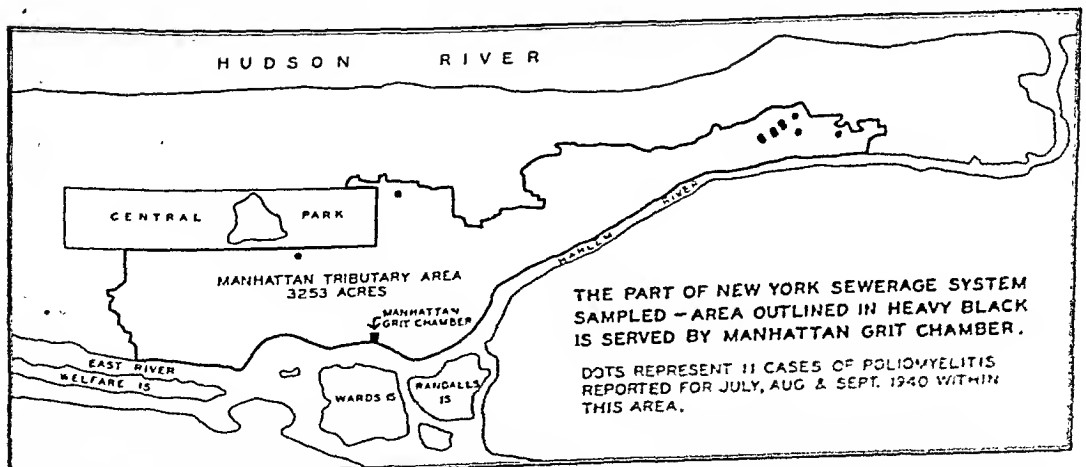

FIGURE 1—An outline map which includes the northern part of Manhattan Island and indicates the geographical relationships of poliomyelitis cases to the site (Manhattan Grit Chamber) where poliomyelitis virus was detected in September, 1940

when cases of poliomyelitis had reached a peak for the year in that city. In 1941 a positive test was obtained in October, following an increase in local cases during August, September, and October.

Regardless of the significance of this finding, the periodic testing of sewers as an index of local case prevalence of the human disease may eventually turn out to have some practical value. It is not clear as yet what its degree of practicality may be, for one does not always find the virus of poliomyelitis in urban sewage in epidemic times.* Our methods for the detection of poliomyelitis are still crude, perhaps when they are improved the value of this technic can be judged in better fashion. So far, poliomyelitis virus has never been isolated from "river water" or from bathing beach water. A single questionable report from well water made in Sweden²⁰ would not fulfil the criteria which are demanded for a positive test in this country.

From circumstantial evidence, however, there has been reason to suspect certain polluted streams as occasionally being of significance from the standpoint of the spread of poliomyelitis. I refer to the suspicions of Caverly in Vermont in 1894, which he directed toward a polluted stream known as Otter Creek in Rutland County, Vt.,²¹ and to the many observations made by Kling in Sweden where he developed his *theorie hydrique* which concerns the association of the disease with water courses.^{22, 23} In this connection it is obvious that, during the summer, polluted water comes in contact with many living things and the question arises as to whether animals, birds, or insects may not act as intermediate hosts be-

tween the "reservoir" of the virus and man, such as is suspected in other summer virus diseases which attack the central nervous system in man, like equine encephalomyelitis of the Eastern and Western types, and St. Louis encephalitis.

A new finding which has only recently come to light and which may or may not have considerable significance in the epidemiology of poliomyelitis is the isolation of the virus of poliomyelitis from flies.²⁴ This has been done on two separate occasions in epidemics in Connecticut and Alabama. In both instances the "contaminated" flies were caught within areas where the prevalence of poliomyelitis was high and where proven human carriers were known to exist.* In both instances the flies had had the opportunity of feeding recently, both in and outside of privies, on human stools which may well have contained the virus. The possible carriage of the virus by these insects would explain much about the baffling nature of this disease. It is undoubtedly a problem which deserves grave consideration by the sanitary engineer.

In conclusion, therefore, recent work (whether rightly or wrongly) has served to place poliomyelitis among the intestinal diseases rather than among the respiratory diseases. It has been suggested that principles of control may eventually turn out to be somewhat similar to those which have been employed with success in typhoid fever or dysentery. These measures do not seem justifiable at present, because of limited knowledge and because of certain differences between poliomyelitis virus and *Escherichia coli*. The differences are, that poliomyelitis virus is so much more stable, and more resistant to chemicals.

* Even during epidemic times individual sewage tests may be negative. This we have encountered in tests made on sewage from Detroit and Frankenmuth, Mich.; Windsor, Canada; and Buffalo, N. Y., in 1939; Waterbury, Conn., in 1940; and in Miami and Pensacola, Fla.; Cleveland, Ohio; and Winnipeg, Manitoba, during 1941.

* Since this paper was written two other reports have appeared by Sahin and Ward,²⁵ and Toomey²⁶ which also describe the isolation of poliomyelitis virus from flies collected within epidemic areas.

Furthermore there is no assurance that the methods used successfully to purify and disinfect material contaminated with typhoid bacilli, for instance, would be successful with poliomyelitis virus. We are, as a matter of fact, quite in the dark as to the control of any virus disease which is also an intestinal disease. And in the control of poliomyelitis our ignorance remains profound. Among other things we still have to wait for more knowledge regarding the significance of insect vectors, and also regarding the existence (during epidemics) of other possible extra-human carriers of the virus, such as mammals or birds.

Opsonocytophagic Reaction to Whooping Cough Vaccination

With Particular Reference to the Effect of Age upon the Response*

ALVIN E. KELLER, M.D., J. CYRIL PETERSON, M.D., AND
PAUL M. DENSEN, D.Sc.

Department of Preventive Medicine and Public Health; and the Department of Pediatrics, Vanderbilt University School of Medicine, Nashville, Tenn.

IN recent years efforts to find an immunizing agent against whooping cough have been intensified. The fact that approximately 60 per cent of the fatalities from whooping cough occur in infants less than one year of age makes it important that any vaccination procedure developed to control the disease be efficacious in the very young infant. It seemed desirable, therefore, to study the serological responses of children of various ages, particularly young infants, to pertussis vaccine prepared by the method of Sauer.

Such an investigation would have point only if it is assumed that the vaccination procedure is effective in conferring immunity. Soon after the organism now called *Hemophilus pertussis* was isolated from cases of whooping cough by Bordet and Gengou attempts at immunization against this disease were carried out. The earlier reports of such attempts seemed favorable, but subsequent reports were unfavorable. In 1925, however, Madsen¹ reported on the modification of whooping cough by the use of vaccines during an epidemic in the Faroe Islands. The report of Leslie and Gardner in 1931² on the

degeneration phases of *Hemophilus pertussis* when grown on artificial media suggested that the vaccine of Madsen owed its potency to the fact that it was prepared from recently isolated strains of the organism.

In 1933,³ Sauer published the first of his reports on the use of large injections of a vaccine prepared from recently isolated strains of *Hemophilus pertussis* grown on a medium which retards degeneration. He was able to show that the vaccine conferred an apparent immunity. Subsequently, these studies have been confirmed by field trials with similar vaccines by Kendrick and Elderling,⁴ Silverthorne,⁵ Singer-Brooks,⁶ Miller and Faber,⁷ and others.^{8, 9, 10} Doull and Shibley and their coworkers in a similar study were unable to show substantial protection against the infection or modification of the disease. They used a vaccine which differed from Sauer's in that the bacteria were washed once with distilled water.

Table 1 summarizes the results of some of the field studies on whooping cough vaccination. Variation in these results may be explained in part on the basis of the differences in the preparation of the vaccines and in the dosage used. This table suggests that large doses of a properly prepared *Hemophilus pertussis* vaccine may confer a certain

amount of immunity.[†] Acting on this assumption the serological responses of infants and older children following injection of pertussis vaccine were observed and compared to see whether there were any differences.

MATERIAL AND EXPERIMENTAL METHODS

The children selected for our investigation were patients attending the outpatient pediatric clinic of Vanderbilt University Hospital. They ranged in age from 6 weeks to 3 years and included 331 white and 50 negro children. Because of the small number of negro children no attempt has been made to study the two races separately. Selections were made on the basis of freedom from active disease processes and upon the desire and the ability of the mothers to coöperate. Most of the children were healthy infants who were being followed in the clinic for regulation of their diets and for routine immunizations.

The observations reported in this paper cover the period from October, 1938, to January, 1941. The children

have been divided into two groups, A and B. Group A consists of 293 children who received a course of vaccination in a 4 weeks' period, plus 44 children who had not completed their course of vaccination but who had adhered to the vaccination schedule up to their last observation. The total number of children in Group A, therefore, is 337. The age distribution of these children is as follows:

Age	Number of individuals
Less than 3 months	74
3- 5 months	89
6-12 months	79
Over 1 year	95
	<hr/> 337

Group B consists of 44 children who received the same total amount of vaccine as those in Group A, but the injections were irregularly spaced over a period ranging from 5 through 10 weeks. The age distribution of the children in Group B is essentially the same as that of the children in Group A.

As far as could be determined by careful questioning of the mothers, none of the children in either group had had whooping cough previously. The great majority had had no known exposure to

[†] Since preparation of this article Rambar, *et al.*,¹² have reported another study indicating that "there is a definite reduction in the incidence and severity of whooping cough following vaccination with phase I, *Hemophilus pertussis* vaccine."

whooping cough and care was taken in the clinic to isolate the children in the study group from known contacts of whooping cough cases. Excluded from the study group were all children who developed pertussis any time within 6 weeks after the initial injection.

There were 57 children who started but never completed the vaccination course. This failure to continue was very rarely due to objections to the vaccination, but was in the main the result of the inability of the mothers to bring the children back to the clinic and of general lack of coöperative spirit.

The routine vaccination procedure used was to give a series of five 1 ml. subcutaneous injections of a vaccine containing 20 billion organisms per ml. over a period of 4 weeks. The vaccine was prepared as authorized by Sauer.* The five dose method of vaccination was chosen primarily to avoid injecting doses larger than 1 ml. No reactions either local or general were encountered which were of sufficient severity to warrant either delaying or discontinuing the injections except in the case of one child. This child had a convulsion during the febrile response which usually accompanied the first and second injections. Subsequently, the child was given smaller and finally full-sized doses without recurrence of the convulsions.

Previous studies by others have shown that specific complement-fixing, agglutinating, and opsonic antibodies appear in the blood of patients following whooping cough and after the injection of potent *Hemophilus pertussis* vaccine. Although it is generally conceded that these phenomena of serological activity may be the result of varying expressions of a single antibody, the precise relationship of this antibody to immunity is indefinite. In this study the opsonocytophagic test employed by Kendrick and her coworkers¹³ was used as a measure of

the antibody response.† This test was chosen because of the ease with which it could be performed. Kendrick found that the tests are negative or weakly positive in normal individuals and that an attack of whooping cough or injections of whooping cough vaccine induces a rise in opsonins, and that the reaction has a satisfactory degree of specificity.

Stained films were prepared and 25 intact polymorphonuclear neutrophilic leucocytes were examined and classified according to the estimated number of bacteria per leucocyte. Those cells showing no phagocytosed bacteria were called negative and the cells containing bacteria were classified as follows: 1-5, 6-20, 21-40, 41-100. This gradation does not necessarily represent a proportionate increase in pertussis antibody, but is merely a convenient classification. The average number of bacteria per leucocyte was then determined for each test performed. A certain number of tests were found to be unsatisfactory. In most instances this was due to inadequate mixing of the citrate and the blood with resulting clot formation. In tests from some of the smaller infants it was difficult to find 25 satisfactory cells in a stained film. These unsatisfactory tests have been noted in the tabulations.

Plate I shows photomicrographs of leucocytes with varying degrees of phagocytosis.

The opsonocytophagic tests were usually performed before the first injection of vaccine, at the time of the fifth injection, and 2 weeks later. Scattered tests were made during the vaccination and afterward at varying weekly intervals when vaccinated children returned for various reasons.

RESULTS

Table 2 and Figure 1 show the opso-

TO PERTUSSIS VACCINE

activity, 16, 31, and 41 bacteria or more per leucocyte respectively.

In the control tests for Group A, only 11.8 per cent of the individuals showed any phagocytic activity at all and in almost all of the instances where phagocytic activity was found the number of bacteria phagocytosed was less than 6 per leucocyte. Approximately the same degree of phagocytosis was found in tests run 1 week after the first injection. Two weeks following the first injection the per cent of tests showing phagocytosis rose to 36.1 and then rapidly to 95.8 per cent by the end of the 6th week following the first injection.

However, inasmuch as some control test may show phagocytic levels of 1-5 bacteria per leucocyte, phagocytosis of this degree in subsequent tests should not be considered significant, although

this phagocytic action may actually represent a response to the injections. On this basis, 91.6 per cent of the individuals 6 weeks after the first injection showed an increase in phagocytic activity. Of the individuals tested at this time 85.5 per cent showed levels of phagocytic activity of 16 bacteria or more, and almost half showed 31 bacteria or more. It is also seen that by the 7th and 8th weeks after the first injection (3 and 4 weeks after the completion of the course of injections) the curves of response have begun to level off. While the tests performed 3 or 4 weeks after the last injection are relatively few in number it seems probable that the maximum of the serological antibody response occurs somewhere in the neighborhood of 2 to 3 weeks following the last injection.

FIGURE 2

OPSONOCYTOPHAGIC RESPONSE OF CHILDREN IN GROUP A
TO PERTUSSIS VACCINE ACCORDING TO AGE

Further examination of the data for Group A (Tables 3, 4, 5, and 6 and Figure 2) reveals progressive changes in the response to vaccination according to the age of the individuals tested. In the control tests of the age group less than 3 months no phagocytic activity was ever found, while in the control tests of the group 3 through 5 months of age, 8.3 per cent showed phagocytosis. This figure rose to 23.7 per cent in children older than 1 year. In only two instances, however, was the degree of phagocytosis on the control test greater than 5 bacteria per leucocyte. Both of

these instances occurred in children in the oldest age group, one of whom showed phagocytosis of 6 to 10 bacteria and the other 21-30 bacteria per leucocyte.

It is shown in the graphs that one result of the aging of the individuals is an increase in the rapidity with which phagocytic activity is induced. Two weeks after the first injection of vaccine there was found with each higher age group a greater percentage of tests showing 16 bacteria or more per leucocyte. In the two oldest age groups there were even a few tests showing 31

bacteria or more per leucocyte at this time. By the 3rd week all of the age groups except the youngest showed a few tests with 41 bacteria or more per leucocyte. The consistent increase with age of both the amount and degree of phagocytic activity up to about the 4th week after the initial injections suggests that the earlier response of older individuals may be associated with the general increase in phagocytic activity

with age which is shown by the control tests.

Six weeks after the initial injection of vaccine, with the exception of the youngest age group, the earlier response of older individuals to antigenic stimuli had little influence with respect to the levels of phagocytosis reached at this time. This point is so similar in the age groups over 3 months as to indicate that the maximum level of phagocytic ac-

tivity may be the same for these ages. For infants under 3 months the response 6 weeks after the first injection is not as great as in the older ages.

To determine the effect of irregular spacing of the vaccine injections on the response to vaccination, Table 7 was prepared showing a comparison of Group A and Group B. The comparison is made 2 weeks after the 5th injection of

vaccine since it is not feasible to examine the responses of Group B except at a definite period after completion of the course of vaccination. It is apparent from Table 7 that the extra periods of 1, 2, and 3 weeks between different injections at varying stages of the vaccination course had very little effect on the degrees of phagocytosis demonstrated 2 weeks after the last injection.

RESPONSE AFTER STIMULATING INJECTIONS

Observations were also made to determine the effect of a single stimulating injection of vaccine on the opsonocytophagic values when administered to vaccinated individuals sometime after the original course of vaccination. Due to difficulties in maintaining contact with patients over a period of many months it was not possible to accumulate any sizeable experience with the response following stimulating injections. We have, however, succeeded in getting 48 children back for both the stimulating injection and a later test. Control opsonocytophagic tests were performed at the time of the stimulating injection and response tests were made 2 weeks later. The stimulating injections were given subcutaneously and the size of the dose was either 0.5 ml. or 1.0 ml. These observations were made usually a year after the primary vaccination, but in a few instances the time interval was as short as 6 months.

Stimulating injections were also given to a group of individuals who had received the "standard" Sauer's vaccination * 1 to 5 years before. The dose

for these individuals was 0.25 ml. given subcutaneously. These children were private patients and as a whole were considerably older than the clinic group.

Table 8 shows the level of opsonins at the time of the stimulating injection compared with the response observed 2 weeks later, according to the size of the stimulating injection. It is apparent that there is a rise of opsonins following the injection of a small stimulating dose of antigen. Comparison of the magnitude of response to the different size doses cannot be made, however, because of the differences in age distribution and the length of time since vaccination of the three groups. However, those children in the clinic group who received 1.0 ml. of vaccine as a stimulating dose showed a rise comparable to that attained following primary vaccination.

In 2 individuals in the tables shown and in 3 others whose tests have been left out because the time of the tests was irregular, we observed a decline in opsonins following the stimulating injections. Of these individuals, 3 were in the group who received 0.25 ml. as a stimulus and 1 each in the groups receiving 0.5 and 1.0 ml. Prior to injection all of these children had a relatively high level of opsonic activity and the degree of decline was never more than from one class to the next lower class.

SUMMARY AND DISCUSSION

Various field investigations of whooping cough vaccination procedures have indicated that large doses of a properly prepared *Hemophilus pertussis* vaccine produces immunity in a large proportion of the children. Assuming this to be true it seemed particularly desirable to investigate the effect of age on the serological responses of children to such vaccination.

* This consists of administering a total of 8 ml. of vaccine containing 10 billion organisms per ml. over a period of 3 weeks, 1.0 ml. being given bilaterally the first week, and 1.5 ml. bilaterally the second and third weeks.

The measure of antibody response to whooping cough vaccination which we have used in this study is the opsonocytophagic reaction. It was recognized that the exact relation of this reaction to immunity is difficult to define, but it does not seem probable that a high degree of immunity can be developed without an opsonocytophagic response. Viewed in this way the results of the opsonocytophagic tests reported here suggest certain points which may be considered in attempting to develop a means for the control of whooping cough.

In this study it has been shown that the majority of infants and young children respond when systematically injected with a properly prepared *Hemophilus pertussis* vaccine by the production of relatively high levels of opsonic activity against the injected organisms. It is particularly noteworthy that very young infants, 6 weeks or more, seemed able to tolerate large injections of vaccine without reactions of serious consequence. The response to vaccination varied with the age of the child. Children under 3 months of age did not respond quite as rapidly as children

over 3 months of age. In general, the older the child the more rapidly a rise in phagocytic activity could be evoked.

It was also noted, however, that the degree of phagocytosis *prior* to vaccination varied with age in the same manner as the results of the opsonocytophagic tests after vaccination. This would suggest that perhaps in the younger infants there has been a lack of previous non-related infections which would serve as stimuli which would condition their response to vaccination.

The rapidity with which the opsonocytophagic response could be induced varied with age, but the capacity to respond seemed the same for all the ages investigated with the exception of children under 3 months.

The above findings have particular significance for the possible development of programs for the prevention of whooping cough by vaccination. The fact that vaccination can be done in the very young infant, where the major problem lies, is encouraging. The data suggest that dosages equal to or larger than those used in older children be used in immunizing the very young child. This and other points of the

vaccination procedure, such as the number of injections, are details which are open for further investigation.

Little information is available on the duration of protective immunity which may follow whooping cough vaccination. In this study relatively high levels of antibodies were found in many of the children a year or more after vaccination, but some of the children showed at that time very little or no phagocytosis. Those showing persistently elevated levels may have had exposure to whooping cough which served to maintain the level or they may represent individuals in whom the antibody level declines slowly, or both.

Although the level of opsonins remained relatively high for some time after the initial course of vaccination, there was a decline from the maximum level of response. The finding, therefore, that a single injection of vaccine 6 months to 5 years after primary vaccination serves to stimulate a rise in the opsonocytophagic response, is particularly pertinent. It suggests the possibility that in the young, where the disease is most apt to be severe and most likely to be attended by a fatal outcome, stimulating injections given at yearly intervals may help to prevent and control the diseases. Such injections may also be given whenever a

familial exposure to the disease occurs.

The best method of administering such stimulating injections requires further study. Further investigation is necessary both in the field and in the laboratory to determine the most feasible method of vaccination as a procedure in the public health program for the control of whooping cough.

Errors in Clinical Statements of Causes of Death*

KURT POHLEN, PH.D., AND HAVEN EMERSON,
M.D., F.A.P.H.A.

*Consultant in Statistics, W. K. Kellogg Foundation, Battle Creek, Mich.; and
Professor of Public Health Emeritus in Residence, De Lamar Institute of
Public Health, College of Physicians and Surgeons, Columbia
University, New York, N. Y.*

THIS is the first of a series of contributions upon the statistical expression of error in certification of causes of death, based upon clinical findings and opinion, when compared with post-mortem protocols of the same cases. The primary collection of data and the plan of study have been under the auspices of the Joint Committee on Autopsies of the American Public Health Association and the American Hospital Association.

It has been planned to assemble records of 100,000 autopsied deaths (1900-1939) occurring in general hospitals where there was full-time pathologist service and a high average ratio of autopsies to deaths. Private funds have permitted the completion of 25,000 records prior to July 1, 1941, and it is hoped that another 20,000 can be obtained in the next twelve months.

Mortality rates as they appear in official reports of vital statistics by health department or other government

bureaus are affected by the two variables of frequency of occurrence and fatality of the respective diseases, and by the degree of accuracy inherent in the process of certification, registration, and tabulation of death returns.

An instance of the confusion and uncertainty as to death rates for an important cause of death was the discussion a decade or two ago concerning the reality of increase in cancer mortality. A definite answer must depend in this, as in similar questions, upon a recognition and correction of errors in clinically established statements of causes of deaths.

Discussions upon errors in clinical statements of causes of death will remain unprofitable until we begin to study by exact statistical methods the problem of diagnostic errors itself. There are only five attempts known to us in the literature dealing statistically with accuracy of diagnostic statements, all comparing clinical statements upon causes of death with autopsy protocols.¹⁻⁴

In addition we have had access to the original text of a paper presented on this subject by George H. Van Buren before the Statistical Section of the American Public Health Association at its meeting in Chicago, Ill., in 1918, but not published.

The data used in the present report

* Read before the Vital Statistics Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

NOTE 1—Dr. Kurt Pohlen has been responsible for the statistical analyses now presented. Drs. Eric Seligmann and Kurt Hirschmann have assisted in the abstracting, sorting, tabulation, analysis and interpretation of the clinical records and autopsy protocols.

NOTE 2—Additional tables and charts not published in the *Journal* because of lack of space may be obtained by writing either author.

of these diseases are due to mentioning secondary stages of such diseases instead of the origin of the infection (e.g., otitis media and encephalitis). Then follow deaths due to accident, the causes of which usually are quite accurately stated.

To give an idea of the methods and results of our study we offer a brief discussion of deaths from malignant tumors. From the records of ten general hospitals, totalling about 20,000 cases, we found 4,051 cases in which either upon autopsy, or by clinical statement of cause of death, or in the admission diagnosis to hospital some form of malignant or unspecified tumor was mentioned. Among the 4,051 cases were 3,462 in which the autopsy report showed some form of malignancy as primary cause of death, including a minority of cases where the tumor was contributory to another disease.

In addition to these 3,462 cases were 271 cases in which the malignant tumor, usually in a very early stage, caused no clinical symptoms and was incidentally discovered in the course of the autopsy as a contributory condition.

The problem of diagnostic accuracy must be considered from two different

and quite independent points of view: the topographic or anatomic site and etiologic diagnosis. A diagnosis is wholly accurate only when both factors, the etiologic and topographic, are correct. All other diagnoses must be looked on as more or less incorrect. The problem is to divide the cases into categories of greater and lesser accuracies. Let us compare for instance two kinds of diagnostic changes by autopsy: first, where clinically an intestinal malignant obstruction was mentioned, which at autopsy proved to have been due to a cancer of the sigmoid, or where the clinical statement was carcinoma of the bile ducts and the corresponding pathologic statement carcinoma of the pancreas with metastases in the bile ducts and colon; and, second, where clinically a liver cirrhosis was observed which proved to be a carcinoma of the liver secondary to cancer of the stomach. In the first two instances the clinical diagnoses were at least partly correct, and in the third case there is a real mistake. We have based all changes of diagnosis upon the autopsy findings. We have classified each diagnosis according to its etiologic and topographic accuracy, and have distinguished five

different expressions of relative diagnostic accuracy, with all possible combinations. As shown in Table 1 we have topographically and etiologically correct, partly correct, and incorrect diagnoses; basing the decision upon autopsy findings and considering whether or not the clinical diagnosis was correct, partly correct, or incorrect. The partly correct diagnoses of malignancies are divided into those where the site of extension of tumor or site of metastasis was incorrectly given for the primary site and those in which inaccurate terms were used, as where the site of malignancy was given only generally as body region or cavity (abdomen, intestinal, etc.). On etiologic classification we divide the partly correct diagnoses into those where another form of malignancy was mistaken for the correct form of tumor (carcinoma versus sarcoma, etc.) or those where the form of tumor was inaccurately described by "malignancy" or "tumor" of which sometimes indicates exclusively a distinct form of tumor and sometimes permits of two or more alternatives. The incorrect diagnoses were both, etiologic and topographic, divided into incorrect but definite diagnoses and cases where no site or cause was given or only a general symptom was mentioned (obstruction, etc.).

Among 3,462 cases of malignant tumors we find 2,311, or two-thirds, correct in both ways, 2,672, or 77 per cent, etiologically correct, and about as many, 2,664, topographically correct. We see that 145 plus 26 cases were etiologically correct but topographically only partly correct, and on the other hand 37 plus 174 cases topographically correct but etiologically partly correct; and that 9 plus 7 plus 48 plus 31 were partly correct under each category. The total of diagnoses considered as partly correct in one or both ways, but in no way completely incorrect is then 477, or

14 per cent. Those diagnoses incorrect under each category numbered 113 plus 28 plus 16 plus 41 cases, totalling 198, or 6 per cent. We must consider as incorrect also those 476 cases which were so either on account of topographic or etiologic error.

By arranging clinical diagnoses by anatomical site in order of per cent of correct diagnoses, we find that the number of entirely correct diagnoses decreases from 96 per cent (breast tumors) to 26 per cent (liver tumors). We always find a high per cent of accuracy in those diseases which can be recognized easily or give marked and characteristic symptoms. An 80 per cent accuracy or more is found for malignant tumors of breast, rectum (including recto-sigmoid), cervix, pharynx and larynx, esophagus. At the other end of the list we find less than 50 per cent correct diagnoses for malignant growths of the liver, small intestine, brain, and bile duct. Since we have recorded in our abstracts also the diagnoses on admission to the hospital we can count the number of cases in which both diagnoses, the admission and final clinical, were correct. This occurred in 1,496 cases, or 43 per cent, chiefly in cases where there had been readmission for the same diseases, from which conditions after previous operations became worse again. The range of such correct diagnoses at both admission and at death is from 87 per cent (breast) to less than 2 per cent (bile ducts) and demonstrates the difficulty of early diagnosis of some deep-seated malignant neoplasms. Details can be seen in Table 2, column 5.

When we compare the ratio between percentages of topographic and etiologic accuracy in the diagnoses of malignant tumors we find for some organs similar percentages, breast (96 and 97 per cent), rectum (89 and 90 per cent), prostate (both 81 per cent), and in other organs the topographic or etiological diagnosis

less correct, as in small intestine 29 per cent topographically, 50 per cent etiologically, and in bile ducts 53 per cent and 70 per cent respectively, while malignant tumors of brain and liver show the reverse conditions with higher accuracy in topographic diagnosis 91 per cent to 31 per cent, and 66 per cent to 44 per cent respectively.

The usual cause-specific mortality statistics apply to only one primary cause, neglecting all contributory conditions. We have concern to know the total frequency of deaths related to a particular disease, disregarding the difference between primary and contributory causes of death. In cases where a malignant neoplasm occurs coincidentally with another disease, preference is usually given in registration practice to the neoplasm. We followed the same rule in our study. But often there are found at autopsy very small early neoplasms which cannot be properly considered as a primary cause of death because they have caused no pathologic symptoms. The ratio of

those contributory malignant growths to the primary cause of death depends upon the speed of growth and upon the symptoms which such small neoplasms make.

We find high percentages of clinically undiscovered neoplasms in the intestine, especially the small intestine, in the prostate, kidney, and thyroid, while bones, lymph nodes, esophagus, pharynx and larynx seldom show a clinically undiscovered neoplasm. This is, so far as bones are concerned, partly due to the limitations of profitable clinical examination.

The discussion of accuracy of malignant tumors would not be complete if we did not mention those cases where a malignant neoplasm (or an unspecified tumor) was clinically diagnosed, which by autopsy was proved to be another and non-malignant disease. In 148 instances such incorrect statement was made, relatively most frequently with regard to the liver, pancreas, thyroid, and esophagus. Eighteen times a malignant tumor of the liver with precise

TABLE 3

or inaccurate etiologic cause stated, was clinically correctly diagnosed, and six times such a neoplasm was incorrectly stated. In column 10 of Table 2 we present the number of cases (148) diagnosed at autopsy with the primary causes of death other than malignant tumor.

The complete statistics of primary and secondary (or contributory) factors causing death enable us to judge the prevalence of metastases with respect to primary sites. Some malignant neoplasms tend to spread easily and some do not.

We deal in our autopsy statistics only with those cases of cancer that died from that disease. We do not have, therefore, those cases of breast carcinoma where early cases were successfully treated, such being mostly cases without metastases. As we find that 91 per cent of breast cancer cases had metastases (in our series), we may conclude that breast cancer was fatal in few cases having no metastases. But besides the breast we find an interesting series of other organs, according to frequency of metastases, beginning with ovaries (90 per cent cases with metastases) and ending with bladder (31 per cent with metastases). We find relatively most metastases with malignant tumors of the breast, ovaries, kidney, gall bladder, and uterus, and few with such neoplasms of the esophagus, pharynx, larynx, bladder, sigmoid, and bile ducts. On the average we have for the 18 most frequent original sites of malignant tumors one-third of the cases without, and two-thirds with metastases, and there are about three and one-third per case having metastases.

In Table 4 there are tabulated 6,129 metastatic neoplasms by 37 categories of site related to the occurrence of death attributed to one of 18 primary sites of the neoplasm in 2,736 cases. (We should mention here that the difference between the total number of

deaths due to primary neoplasms of various sites in Table 3 and 4 (column 2) is due to those cases omitted in either study for which there was incomplete data for the one or other item).

We have calculated the ratios of metastatic frequencies to each 100 cases of primary tumors. We find lymph nodes reported as affected by metastases in 42 per cent of all primary sites together, liver metastases in 34 per cent, and lung metastases in 21 per cent. Next in frequency of involvement come peritoneum, 16 per cent, adrenal and pleura 11 per cent. All other sites are involved in less than 10 per cent of the cases.

When we now compare the ratios for the specified primary sites with the corresponding ratios for all primary sites together, we get an expression of the relationship between primary and secondary sites of malignant neoplasms. In Table 5 we have the result of such comparison (quotients of specified site through total of sites). Coefficients higher than one indicate a higher frequency than would be expected by rule of chance, and lower than one indicates a smaller frequency than expected.

We must take into account that often the numbers of cases involved are small and give rise to a considerable statistical error.

We note that primary carcinoma of the stomach tends rarely to metastasize in the breast, but that primary malignant breast neoplasms tend more commonly to metastasize in the stomach; that primary carcinoma of the lung relatively frequently develops metastases of the pharynx and larynx. The only metastases developing in the rectum with over-average frequency are those following primary carcinoma of the prostate. In a complete list every combination of two organs is listed twice, each of both organs being once a primary and once a secondary site. While primary

carcinoma of the esophagus does not tend to metastasize in the gall bladder, we find that the esophagus as site of secondary neoplasms receives its metastases relatively more frequently from primary neoplasms of the gall bladder than from other sites. The highest relation between two organs in our list (Table 5) is that between both single breasts. It must be understood that statistically adequate ratios must await the use of a larger series of case histories for malignant neoplasms in relatively rare sites, both primary and secondary.

It will be obvious that the above analysis of the deaths due to cancer is

of value chiefly at this stage as a test of the method of study and its usefulness in supplying us with some approach to desirable criteria or mathematical indices of error to be expected and to be allowed for when preparing specific cause-mortality rates, based upon clinical diagnoses of varying degrees of inaccuracy or incompleteness.

U. S. Department of Agriculture, Beltsville, Md.*

IN 1939 a method was presented¹ for the evaluation of germicidal compounds in which the toxicity of such substances for a circulating tissue (human or guinea pig blood) was compared with the toxicity of these compounds for a standard strain† of *Staphylococcus aureus*. A toxicity index was computed by dividing the greatest dilution of the compound under test toxic for tissue by the greatest dilution capable of killing the test organism. The mechanism of the toxic action of germicides on whole blood used as a tissue measured by the loss of the phagocytic activity of leucocytes and the use of hemolytic complement to determine the toxic effect were subsequently studied.^{2, 3} Our results showed that although some indication of the toxic effect of germicides could be determined by observation of hemolysis, or coagulation, or by measuring the destruction of hemolytic complement, utilization of the phagocytic function of the leucocyte, as an index of toxicity gave the most exact and consistent results. Germicides tested with this method by different technicians consistently have shown the same "toxic endpoint" and no variations in these

endpoints are observed when different human bloods or different guinea pig bloods are used in the test. A ready reference of the toxic effect of the compounds studied is possible since permanent blood smears may be prepared and kept on file.

In addition to the technical advantages of the proposed method, the use of blood, a tissue which is uniform in its makeup and reaction, to determine the toxic action of germicides approaches the actual conditions of use of these substances in or on the human body more nearly than other tissue methods and, further, the use of the phagocytic function of the leucocyte as an indication of the toxic action of these compounds appears especially appropriate since the purpose of antiseptic substances is to augment rather than retard the natural defenses of the host. In a recent publication, Fleming⁴ points out that "In a septic wound in which the infection had become established, the pus had considerable antibacterial powers which were lost when the cells were killed by heat, drying or by treatment with antiseptics." He further states that "Any chemical which was more destructive to leucocytes than it was to bacteria was very unlikely to be effective as a direct antiseptic in a septic wound."

In studying a group of compounds insoluble in water, the appreciable tox-

† This strain of *Staphylococcus aureus* has a standard resistance to phenol maintained for testing germicidal substances in the Food and Drug Administration, Washington, D. C.

icity of alcohol used as solvent and the marked toxicity of soap solution, used as an emulsifying agent, attracted attention. After obtaining toxicity indices on alcohol and castile soap, the influence of these substances on the toxicity and germicidal action of phenol was investigated. Solutions of phenol dissolved in 50 per cent alcohol and in 5 per cent castile soap solution were used as a dilution basis.

The toxicity of an aqueous solution of phenol for guinea pig tissue has been demonstrated¹ to be 1:500. When 5 per cent phenol is mixed with an equal amount of alcohol before dilution, its toxicity is markedly increased to 1:1,800 and in 5 per cent soap solution the toxicity is further greatly increased to 1:6,500. Correspondingly, the toxicity index increases from 5.0 (phenol in water) to 9.0 (phenol in alcohol) to 43.3 (phenol in soap solution). These results are shown in Table 1. Although the bactericidal dilution of aqueous phenol is 1:100 under the conditions of this test, a 1:200 dilution of an alcoholic solution of phenol is germicidal, and while the use of soap solution as a solvent for phenol increases the toxicity greatly over that of phenol in alcohol, there is not a corresponding increase in germi-

cidal efficiency. On the contrary, the germicidal power is decreased by 25 per cent under that shown by phenol in alcohol.

In testing some essential oils and other compounds insoluble in water, a similar phenomenon was noted (Table 1). Those oils dissolved in alcohol (50 per cent or 100 per cent, depending on the solubility of the oil) were considerably less toxic than when emulsified in 5 per cent soap solution. Perhaps the most striking example is that of thymol which is toxic for tissue in a dilution of 1:2,500 when dissolved in alcohol (50 per cent), while emulsified in 5 per cent soap solution it is toxic in a dilution of 1:18,000. The toxicity indices are correspondingly widely divergent, since an index of 1.3 is obtained with thymol in alcohol and 45.0 with thymol in soap solution. Chlorothymol also shows a similar phenomenon. An excellent index of 0.83 is obtained when this substance is dissolved in alcohol, while a marked increase to 20.0 is found when soap solution is used as carrying agent. It should be noted that since the concentrations of alcohol and soap are also diminished on dilution, the concentration of alcohol at the toxic endpoint of

TABLE 1

Relative Toxicity and Toxicity Indices of Certain Germicidal Substances Containing Soap or Alcohol

* Not germicidal at dilution indicated

CHART I

thymol was 2 per cent and the concentration of soap only 0.03 per cent. In Table 1 it will be observed that all the substances tested showed a marked increase in toxicity for tissue and a definite decrease in germicidal activity when alcohol was replaced by soap as a solvent. For comparative purposes, the toxicity indices of absolute alcohol and the castile soap used in these studies were determined. It will be observed that absolute alcohol is toxic for tissue at 1:30 and germicidal at 1:4, while castile soap is toxic at 1:1,800 and is *not* germicidal at 1:25. The toxicity index of alcohol is 7.5, while that of soap is greater than 72. The differences in toxicity indices, depending on the use of alcohol or soap as a solvent, are shown graphically in Chart 1.

The results presented in Table 1 and illustrated in Chart 1 reveal that the toxicity of the principal substance in an antiseptic solution may be of very minor importance and that of the menstruum may assume the rôle of primary

importance. For example, the toxicity of phenol determined in aqueous solution offers no clue to its toxicity in the presence of even small amounts of alcohol or soap. To a lesser degree the same is true of its germicidal properties; but, as has been pointed out, the two effects are not proportional. It is quite obvious that a substance found to have a comparatively favorable toxicity index may have a relatively unfavorable index in a different menstruum or upon the addition of even small amounts of other substances.

It was demonstrated in a previous paper that a slight increase in the concentration of table salt increased the toxicity of phenol. Thus in the case of the compounds listed in Table 1 which are not soluble in water, the toxicity of the basic substance has not been measured but only that of a combination of substances from which it is not possible to deduce the toxic qualities of the individual components. It should be remembered that the figures given for toxicity are not those dilu-

tions which are sufficiently toxic to reduce phagocytosis but those which prevent all phagocytic activity. In the case of phenol in alcohol, for example, the percentage of alcohol in the final dilution is below the range of absolute toxicity of this substance but not necessarily beyond the limits of all toxicity; and it is not possible to judge whether the toxic endpoint obtained is due primarily to this concentration of alcohol augmented with small amounts of phenol, or whether the reverse is true, or whether the explanation is to be found in a mutually synergistic action. In any event, the increase in toxicity is too great to be accounted for by the additive effect of the two compounds taken singly. It is known that bacterial spores are not killed by alcohol, yet it has been shown in this laboratory (unpublished) that in the presence of a definite percentage of alcohol 5 per cent hydrochloric acid becomes as sporicidal as a 20 per cent aqueous solution of hydrochloric acid. Decreases or increases in the percentage of alcohol give a decreased efficiency. Cade⁵ has shown that the germicidal action of phenol and certain related compounds can be greatly increased by the addition of the proper amounts of soap, and that the optimal amount varies not only with type of soap but with the compound to which it is added. This being the case with germicidal effect, it is logical to suppose that with the apparently much greater sensitivity of tissue to soap, the critical amount is even more important. No attempt was made to determine those concentrations of soap most affecting the toxicity of the various compounds. It should be stated that in some of the dilutions tested in determining the endpoint, complete solubility was not always obtained.

Inasmuch as essential oils are contained in a great majority of mouthwashes, and alcohol is made use of as

a solvent, and since it is common for these preparations to be recommended for use undiluted as well as for application to cuts and scratches or as general antiseptics, it becomes of interest to determine whether they are free of significant toxicity. In the present study toxicity index tests on a group of 87 commercial mouthwashes are included. The results are summarized in Table 2, where the toxicity for tissue and bactericidal power for *Staphylococci* of 87 mouthwashes are given and the toxicity index of each computed. Of the 87 mouthwashes studied, 62 were toxic for tissue in a dilution of 1:5; 14 were toxic for tissue in a dilution of 1:10; 2 were toxic in a dilution of 1:15; 5 were toxic in a dilution of 1:20, and one each was toxic at dilutions of 1:25, 1:30, 1:40 and 1:50.

None of the mouthwashes toxic at 1:5 was capable of killing the standard strain of *Staphylococcus aureus* (209) under the conditions of this test at a final dilution of 1:2.5. The toxicity index in each case was therefore greater than 2.0. Of those mouthwashes in the group toxic for tissue at 1:10, it was possible to compute accurately the toxicity index of only two, Jermene and Pentacresol. These mouthwashes had indices of 2.0 for the former and 4.0 for the latter, and all others in this group had indices greater than 4.0, since none was germicidal in a dilution of 1:2.5. Neither one of the mouthwashes toxic in a 1:15 dilution was germicidal in a 1:2.5 dilution, and their indices were, therefore, greater than 6.0, while 4 of the 5 toxic for tissue at 1:20 were germicidal under the conditions of this test, one in a dilution of 1:10. In this group, Extol had a computed toxicity index of 8.0, Hychlorite Solution an index of 2.0; Mark 4 an index of 2.0; Zonite an index of 2.7; and Salzinco, which was not germicidal at 1:2.5, had an index greater than 8.0. Of the remaining 4 mouth-

washes in this series, Fo-fen-x, Gilbert's, Astring-o-sol and Afko, "toxic end-points" of 1:25, 1:30, 1:40 and 1:50, respectively, were obtained. All but Gilbert's mouthwash were germicidal at a 1:5 dilution. This mouthwash, being not germicidal at a 1:2.5 dilution, had an index greater than 12, while the toxicity index of Fo-fen-x was 5, that of Astring-o-sol 8, and Afko 10. It should be noted that the toxicity index number represents the number of times the mouthwash is more toxic for tissue than it is for the test organism. It will be remembered that in determining the toxicity index, both tests contain whole blood; the toxicity test 40 per cent, the germicidal only 10 per cent, and that toxicity is measured not at the dilution affecting normal phagocytosis but at the weakest dilution which prevents all phagocytic activity.

It is of interest that of the 76 mouthwashes tabulated and found to be toxic at a 1:5 or 1:10 dilution, 56 of these are *Liquor antisepticus* type, while of the 11 remaining in this series toxic in dilutions from 1:15 to 1:50, only one is definitely this type. Of the 87 mouthwashes tested, only 9 were germicidal under the conditions of the test, and these varied in their indices from 2 to greater than 12. It is quite apparent that those mouthwashes showing definite germicidal power correspondingly showed greater toxicity for tissue. Of the 62 found to be toxic when diluted 1:5, 54 are offered for use undiluted; furthermore, 9 of the 14 found toxic in a 1:10 dilution bear a similar recommendation. Of this group toxic at 1:5 or 1:10, 74 of the 76 so-called antiseptics were unable in 30 minutes to kill all *Staphylococcus aureus* present under the conditions of this test.

COMMENT

In presenting the above data, no

thought of discrimination or special examination is connected with any of the preparations used. Indeed, the results amply show that no special credit or discredit can be ascribed to any individual preparation or type of compound. The object in collecting the results is part of a general study of germicidal substances. It is felt that by a comparison of a number of substances tested by different methods and types of methods our knowledge of the effective uses of germicides can gradually be increased.

Although this test possesses considerable practical value, the impossibility of evaluating antiseptics for all their diverse uses by results of this method alone is thoroughly recognized. On the other hand, the results in Table 2 illustrate several generalities perhaps well known but too seldom considered. Not one of the preparations tested approaches the classical conception of an ideal antiseptic. On the contrary, the results demonstrate that if used on cuts, scratches, or open wounds for which purpose many bear recommendations, not only would the majority fail to produce complete germicidal effect but their presence would continue to prevent the normal protective action of the blood after germicidal value was lost. The importance of Fleming's contention, quoted earlier, is emphasized by these figures, which also might well be used to point out the inadvisability and possible harm caused by the indiscriminate use of antiseptics for a variety of conditions and purposes without ample consideration of the results likely to be obtained in a particular condition.

It might be contended that the unfavorable balance between toxicity and germicidal ability of the preparations tested signifies too harsh a test, and that *Staphylococcus aureus*, although comparatively resistant, is by no means the only organism to be combated with

antiseptics. Nevertheless, recognition of *Staphylococcus aureus* as a frequent and sometimes dangerous invader of wounds and of the existence of strains of standardized resistance not only justifies but clearly dictates its use as a test organism for a toxicity method of this kind.

SUMMARY

Using the destruction of phagocytic activity as a measurement of toxicity and comparing toxicity with germicidal ability under a similar set of conditions to obtain a toxicity index, it was found that the addition of alcohol to a solution of phenol increased the toxicity index. A very marked increase in the toxicity index occurred when soap was added to phenol solutions. The relatively high toxicity index caused by the addition of soap was demonstrated with several phenolic compounds and essential oils. The toxicity of alcohol and soap was obtained for comparison. The toxicity and germicidal power of

87 commercial mouthwashes have been determined. Only 9 of the 87 mouthwashes tested were found to be germicidal under the conditions of test, while 62 were toxic in a 1:5 dilution; 14 were toxic in a 1:10 dilution; 2 were toxic in a 1:15 dilution; 5 were toxic in a 1:20 dilution, and one each was toxic at dilutions of 1:25, 1:30, 1:40 and 1:50.

A brief discussion of the application of the toxicity-index method to the evaluation of antiseptics is presented.

Neighborhood Health

WE note with great reluctance the discontinuance for an indefinite period of *Neighborhood Health*, a publication issued by the Department of Health of the City of New York. The Department is dropping this periodical as a part of its program to concentrate all its efforts on the most indispensable public health services during the war.

We are sure that many readers of *Neighborhood Health* will miss this thoroughly instructive and enjoyable publication. The final issue was devoted to a compilation of popularized information on nutrition and was an excellent "swan song" for this valuable periodical.

An Improved Non-Virulent Rabies Vaccine*

L. T. WEBSTER, M.D., F.A.P.H.A., AND J. CASALS, M.D.

*Laboratories of The Rockefeller Institute for Medical Research,
New York, N. Y.*

A NON-VIRULENT rabies vaccine has been developed and tested in our laboratory with results which warrant its trial by others both in the laboratory and in the field.

The vaccine is prepared in the following manner: Two months old beagle dogs are injected intracerebrally with mouse brain rabies virus, Pasteur strain. When the animals are prostrate, their brains are removed, weighed, triturated, and diluted with buffered distilled water to make a 5 per cent emulsion. This emulsion is then centrifugalized at 500 r.p.m. for 5 minutes and the supernatant removed. This supernatant, to immunize, must titer at least 330,000 mouse doses per ml. and be relatively free of large particles. It is then rendered non-virulent by exposure to ultra-violet light for 35 minutes. Tests for sterility are made and the vaccine is then ready for use.

This vaccine has been submitted to four types of test, each of which will now be summarized.

Our intracerebral test¹ was first employed with modifications designed to reduce both the amount of vaccine and the number of doses required. Three intraperitoneal doses each of 0.03 ml. of vaccine immunized mice effectively.

This is the smallest total amount and fewest doses of vaccine yet found effective against a subsequent intracerebral injection.

To permit a comparison of irradiated vaccine with others designed for human treatment, commercial phenolized and chloroformized vaccines and our irradiated vaccine were diluted as previously described.¹

The dilution of vaccine eliminates the effect of phenol and chloroform.

The irradiated vaccine protected mice against 10,000 lethal doses and the

* 6/6=6 mice died of 6 injected

—=Dilution not tested

We designed the intramuscular test¹ for vaccines with too slight immunizing potency for detection by the intracerebral method. The test simulates natural conditions and permits critical testing of canine vaccines. A single injection of 0.1 ml. of irradiated vac-

cine is ample to immunize mice consistently against street virus injected intramuscularly.

A third type of test not previously described has been that of infection with virus followed by treatment with vaccine. Groups of mice are given 0.01 ml. of street virus in dilutions into the gastrocnemius muscle and vaccine injections are commenced 3 hours later. Non-vaccinated mice show incubation periods exceeding 14 days and numerous survivors. No phenolized vaccine has given a clear-cut protective effect; chloroformized vaccines occasionally show some. The irradiated vaccine, however, in 5 doses totaling 0.5 ml., prevents rabies in most instances.

TABLE 3

TABLE 5

Immunity of Vaccinated Dogs to Rabies Virus Injected Intramuscularly

Dogs	Controls	Phenolized Vaccine	Chloroformized Vaccine	Irradiated Vaccine
Number tested	162	62	52	59
Number dead	136	45	26	1
Per cent dead	84	72	50	1.7

The final experiments dealt with the immunizing effects of irradiated vaccine in dogs. For 3 years young beagle dogs have been tested for resistance to rabies by injecting early-passage street virus into the neck muscles. Of 162 unvaccinated dogs injected with virus, about 84 per cent died. Of 62 dogs given commercial phenolized vaccine 3 weeks prior to the test injection of virus, 72 per cent died. Of 52 given chloroformized vaccine, 50 per cent died. Of 35 given 30 to 40 ml. of irradiated vaccine in a single dose, all were protected save one; of 24 given 5 to 10 ml. of the vaccine concentrated 6 times, all were protected.

In summary, the experiments have shown that the irradiated rabies vaccine is superior to other vaccines now on the market for immunizing mice and dogs against rabies. The vaccine can be prepared within 7 days, released within another 7 days, is relatively free from brain tissue, and appears quite harmless. Finally, its potency and, indeed, the steps in its preparation can be checked quantitatively.

HERBERT H. HASSON

Engineering Director, W. K. Kellogg Foundation, Battle Creek, Mich.

PROBLEMS of personnel and personnel functions in the field of environmental sanitation are receiving increased attention from those interested in public health engineering. This interest is reflected in the discussions of fellow workers, in committee work of the American Public Health Association, and in current publications.

In reviewing some of the published material concerning this field of interest, it is evident that one of the major questions under discussion is whether it is practicable and desirable to use trained sanitary engineers for the environmental sanitation work in the smaller units of public health organization. In most cases, it has been generally accepted in theory, if not in fact, that the training of the public health engineer is the minimum preparation necessary to direct the sanitation activities properly in the larger administrative divisions. The acceptance of such a premise concerning the smaller units has not as yet taken place due largely to economic considerations. The rôle of the public health engineer in the smaller administrative units has been ably presented by others,^{1, 2, 3} and need not be repeated here. Perhaps one of the reasons that economic considerations play such a strong part in decisions to use less well qualified personnel in the smaller administrative

units is the failure of officials to take the time to view in perspective the type of environmental sanitation program which will most effectively and positively influence the planning, design and building of a safe and healthful community.

The experience of seven rural county health departments in southwestern Michigan may, perhaps, throw some light on this question. To a certain extent these county units, coöperating in the Michigan Community Health Project, have unusual resources through the coöperation of the W. K. Kellogg Foundation. Nevertheless they are responsible for the customary public health program including environmental sanitation.

These rural areas have the usual problems of water supply, excreta disposal, milk and food supply, resort sanitation, school hygiene, housing, and those sanitation problems found in small industries.

When the health departments were first established, few of the public water supplies were satisfactorily protected. The percentage of bottled milk that was pasteurized was very low, and other protections usually considered as necessary to a healthful environment were correspondingly poor.

The first step in the approach to the solution of the problems of these counties was one of definition with all that this involves if intelligently done including inspections, tabulations, charts,

* Read before the Conference of Municipal Public Health Engineers at the Seventieth Annual Meeting of the American Public Health Association in Atlantic City, N. J., October 13, 1941.

maps, and analysis of facts. Standards had to be agreed upon based on the pooled experience of qualified authorities and as translated into terms of the local situation.

Once defined, a properly qualified person not only applied his technical knowledge to the individual problems of pasteurization equipment, approval of plans for new or improvements to existing water supplies, etc., but he developed a plan of attack, with the approval of the health officer. Together they interpreted the problem to the officials and people of the community in a scientifically correct and forceful manner. Once the people of the community understood, for example, the benefits resulting from the use of a safe water supply and a safe milk supply, and once they understood the procedure necessary to obtain these services, and once the people who supply these services understood their responsibilities, then improvements came as day after night. Both the educational program and the technical program were scientifically sound and convincing.

There is no one way by which a person or a group of people can be influenced on a given subject. The program was directed by both the Health Officer and the engineer to the school board, the school teacher, and the school child; the local physician; the dairyman; the veterinarian; the milk plant owner; the local service club; the newspaperman; the camp to which the child goes; the parents; the motion pictures, etc. All of these factors and more may have a bearing, for example, on a person's attitude toward whether the milk served in the school is pasteurized or raw. A planned specific approach to a program of education directed at the proper points will yield dividends much more readily than a program that has not been properly defined nor adequately understood and accepted by the community. The program of the public

health engineer takes into consideration the driving forces that motivate the people he is dealing with.

In the campaign to improve the milk supply the health officer can usually obtain the coöperation of the medical and dental societies, the veterinarians' association, and others that are directly concerned, in the consideration of the scientific facts regarding the effect of pasteurization on milk and in the endorsement of the use of safe milk.

Furthermore, it is important to the progress of the program that the large consumers of milk demand a safe milk. It is important that the people who buy milk for schools, hospitals, camps, and restaurants, for sale or distribution to others buy safe milk. Health departments can influence most of the restaurants and resorts to want a safe milk supply and then should take the positive stand that all establishments must sell only milk that is properly pasteurized. A concentration of all the health department programs that affect milk must be achieved.

It is readily seen that the health officer with a public health engineer has open to him quite a different approach to the problems of environmental control from that of routine inspection of facilities in the field to determine whether sanitation standards are met or whether the law is being complied with.

What applies to the milk situation also applies to problems in connection with a municipal water supply.

For example, in securing the extension of water mains into certain areas of a municipality, that the village fathers in the past had decided could not be served, similar problems are presented. There may be in the area of the municipality eight families living on a street that have been told that the water mains cannot be extended to them because there are not enough connections to justify the first cost. They then have to construct their own water supplies

which may or may not be safe. Later, four more families build on the same street and want water from the municipality. Perhaps with the twelve families there are enough customers to justify the expense involved. But by this time the first eight families, who have spent considerable money to obtain their own supplies, will have nothing to do with the village water. Without question, such a situation requires a knowledge on the part of the public health engineer of the principles of water supply protection, but it also entails an understanding and the application of, let us say, community engineering of the highest caliber to secure the best solution. Such community engineering embraces the problem of securing the coöperation of the village fathers in a consideration of the economic and social problems involved as well as the public health problems. From such an understanding the village council may be expected to assume an attitude which will result in action.

Small semi-public water supplies present the same type of problem. The inspector goes to the school and finds that the well is driven within a few feet of the septic tank. It is obvious that all such dangerous conditions must be corrected, but it is far more important that, from that time on; no future improperly located or protected installations of such a nature be made. This means a positive preventive program, educational and coördinated in plan, for well drillers, plumbers, contractors, school authorities, and others who have a direct relationship with the problem. It is not enough to correct conditions that exist or to make inspections to see if accepted sanitation standards are met. The program, to be effective, must be a positive one to insure that all new work will be done properly. That can be accomplished only when the people who are doing it understand the basic principles of location, construction, and protection of wells, and the people who are having

it done understand the necessity for such procedures.

It is certainly desirable to have the school water supply protected, to have the restaurant clean, the milk supply safe, and to have proper and safe systems of excreta disposal. The public health engineer in a rural community has to find ways to make the people want to reach health objectives through their own interest and understanding of the problems.

When a field visit is being made the public health engineer is able to contribute effectively to the accomplishment of an educational goal. To record the number of field visits made, means little. It is most important that the contact be educational. The field forms should be such that the owner of the establishment can see what facilities are necessary and to understand why. It is to his benefit to know.

The office forms containing information secured in the field should be designed for use gradually to develop the community picture, to show needs, to show progress, and to assist in understanding problems and developing sound policies and programs.

It will be recognized that these same factors operate throughout the entire environmental sanitation program. The problems are community ones to be solved through the educational, social, and economic considerations as well as through the application of technical engineering principles. As a consequence, community hygiene plans and programs should be developed on the basis of active participation of the people and groups concerned. Proceeding on this line of reasoning it is apparent that trained individuals can accomplish the objectives much more effectively than can less well qualified personnel. The health officer is more likely to permit properly trained personnel to engage in a far-reaching educational and coördinated type of program which he feels is

basically sound than he will if he has to depend only on less well qualified personnel.

We believe that the fundamental differences between the value of the public health engineer and a less well qualified inspector are apparent when one visualizes such an attack on community sanitation problems.

The approach to these community environmental problems should be on a problem solving basis. First, comes the finding of the problem; second, comes the education of those directly concerned to see the problem; and third, comes the organization of the community resources to help solve the problem. Another way in which we like to think of the problem solving approach is the "what," "why," and "how."

In conclusion, it should be stated that the less well qualified inspector has a place at this time in the cities and larger units of public health organization when working under qualified engineering di-

rection. However, it is felt that the inspector and his program cannot be superimposed on a rural community without technical engineering supervision, unless the local department is willing to accept a less effective type of sanitation program. It appears to us in the Michigan Community Health Project that the public health engineer with his background of basic training which equips him to enlist and coordinate the community forces is a sounder investment to a small county health unit than a less well qualified inspector working independent of qualified engineering direction.

Carriers and Abortive Cases in a Rural Poliomyelitis Outbreak*

ALEXANDER D. LANGMUIR, M.D., F.A.P.H.A.

*Deputy Commissioner, Westchester County Health Department,
Peekskill, N. Y.†*

FOUR children in the Town of Knox, a rural area in Albany County, N. Y., became ill with severe paralytic poliomyelitis on the same day, September 10, 1940. A 5th similar case developed on the following day. Three of these cases occurred in one family.

No case of poliomyelitis had been reported previously in this sparsely populated community since 1922. Although only 5 paralyzed cases were observed, the morbidity rate among the 953 residents in the Town of Knox was 5.3 per 1,000, a rate for paralyzed cases comparable with those seen during the severest epidemics in urban areas.

The Town of Knox is located in a corner of Albany County bordering on Schenectady County. It consists of farms and one small hamlet of 25 to 30 houses. A paved road makes the town readily accessible to the cities of Schenectady and Albany, approximately 12 and 22 miles distant, respectively.

During the 2 months preceding the Knox outbreak, 17 poliomyelitis cases were reported in Albany and Schenectady Counties. Ten of these were in the city of Schenectady and its suburban areas, Rotterdam and Scotia. During the preceding decade, 1930 to 1939, only once had the incidence of poliomyelitis in Schenectady County

been higher than in 1940, and that was 9 years earlier in 1931. From 1936 to 1939 there had been only one case reported each year. Thus the Knox episode was preceded by a higher than normal prevalence of poliomyelitis in nearby areas.

METHOD OF INVESTIGATION

Field and laboratory studies were inaugurated ‡ on September 16, the diagnosis in all 5 paralyzed patients having been confirmed by their clinical course and lumbar puncture findings.

With the assistance of a public health nurse, a household canvas was made in each home situated within an area of approximately two miles radius, centering about the 3 families in which paralytic poliomyelitis occurred. The survey was started on September 25 and completed on October 4. In each home a household roster was taken and notes were made of the history of any illness, no matter how slight, during the period September 1 to 24. All the symptoms commonly associated with abortive poliomyelitis were specifically mentioned. Individuals found to have had symptoms suspicious of this condition were checked by an orthopedic nurse trained in muscle grading. No undiscovered cases with paralysis were recognized.

Stool specimens for monkey inoculation were collected from the 5 paralytic

cases, from all of their household contacts, from a 4th family, intimately associated with one of the paralytic cases, in which suspicious illnesses had occurred, and from 8 other individuals in whom no contact was discovered. All specimens were collected between September 16 and October 5, the majority being taken from 2 to 3 weeks after the outbreak occurred.

These stool specimens were examined in the Division of Laboratories and Research of the New York State Health Department, by Dr. George Y. McClure. The technic used was a modification of the procedures developed by Trask, Vignec, and Paul (1938), and consisted of the intraperitoneal inoculation of rhesus monkeys with the stool specimen after treatment with ether and lauryl sulfate. Some of the monkeys were also given simultaneous intra-nasal inoculations. A detailed report of the

laboratory results is being published by McClure and Langmuir.

SURVEY OF ILLNESSES IN THE COMMUNITY

In addition to the paralyzed cases, a number of acute minor illnesses were discovered in the community. The number of individuals surveyed, the total persons with illnesses, and the attack rates, according to age and association with the poliomyelitis cases, are presented in Table 1. The 33 intimate associates consist of 20 household contacts of the paralytic cases, and 13 close friends of the family in which 3 paralyzed cases occurred. The age adjusted attack rate among the intimate associates is double the rate among the others in the community. This difference is of doubtful statistical significance due to the small number of intimate associates; however, the dif-

TABLE 2

Classification of Types of Symptoms Reported in Survey of Acute Illnesses, Knox, N. Y., September 1-24, 1940

<i>Upper Respiratory</i>	<i>Gastrointestinal</i>	<i>Nervous System</i>
Cold in head	Nausea	Pain in extremities
Coryza	Vomiting	Sciatica
Cough	Anorexia	Backache
Sneezing	Diarrhea	Headache
Sore throat	Pain in abdomen	Stiff neck
Ear ache	Gas on stomach	Dizziness
Tightness in chest		Drowsiness

ference is consistent both among the children and the adults.

The acute illnesses have been classified into 3 groups by symptoms referable to the upper respiratory, gastrointestinal, and central or peripheral nervous systems. The symptoms included in these 3 classifications are listed in Table 2.

The number of acute illnesses, by age and according to type of symptoms and association with poliomyelitis cases, is presented in Table 3. Although the numbers are quite small, rather striking difference in attack rates occurred, as shown in Table 4. The illnesses referable to the gastrointestinal and nervous system predominate among the intimate associates, while the upper respiratory illnesses are concentrated among the others in the community. As with the rates for total illnesses, the differences are of doubtful statistical significance, but they are fairly consistent for both children and adults.

LABORATORY FINDINGS AND CLINICAL OBSERVATIONS

A summary of the results of the examinations of the stool specimens is presented in Table 5. Four of the 5 paralytic cases were found to have poliomyelitis virus in their stools. In the 5th case, doubtful results were obtained which have been discussed in a special report by McClure (1941).

Thirteen of the 27 contacts from whom specimens were obtained gave a history of illness. The onset of symptoms in each of these cases occurred within the 10 day period, September 10 to 19, immediately following the outbreak. Of these 13 intimate contacts with illness, 10 (77 per cent) harbored poliomyelitis virus in their stools, and therefore, may have been unrecognized cases of poliomyelitis. Only 1 of these 10 individuals gave a history of fever which is the basic criterion set by Paul, Salinger, and Trask (1933) for the diagnosis of abortive poliomyelitis. This

patient, a 3 year old girl, had an acute febrile episode with vomiting and malaise. A physician saw her three times but failed to find stiff neck or evidence of muscular weakness. Four other children had mild stomach upsets with vomiting and abdominal pain about which their mother was wholly unconcerned. Two children had mild upper respiratory symptoms, which did not confine them to bed. The remaining 3, 2 children and 1 adult, had symptoms suggesting involvement of the peripheral or central nervous system. The first, a 13 year old girl, had pain in the knees and backache for one day, but she remained in school. The 2nd, a 10 year old boy, had headache, pain in the eyes, dizziness, and soreness in the chest and abdomen. He was out of school for 2 days but his mother denied that he had had fever. The 3rd, a 43 year old man, developed a severe sciatica which necessitated a visit from a physician on September 14. Although the information available on this case is limited, it suggests the polynuritic form of poliomyelitis described by Wickman (1913).

Of the 3 intimate contacts with illness who had negative stools, 1 adult complained of "gas on the stomach" for one day, another had headache and anorexia, and 1 child had a mild stomach upset with vomiting.

Among the 14 intimate contacts who remained well during the period of observation, 10 (71.4 per cent) were carriers. Out of the total group of 27

intimate contacts, 4 of the 8 adults and 16 of the 19 children harbored the virus at some time.

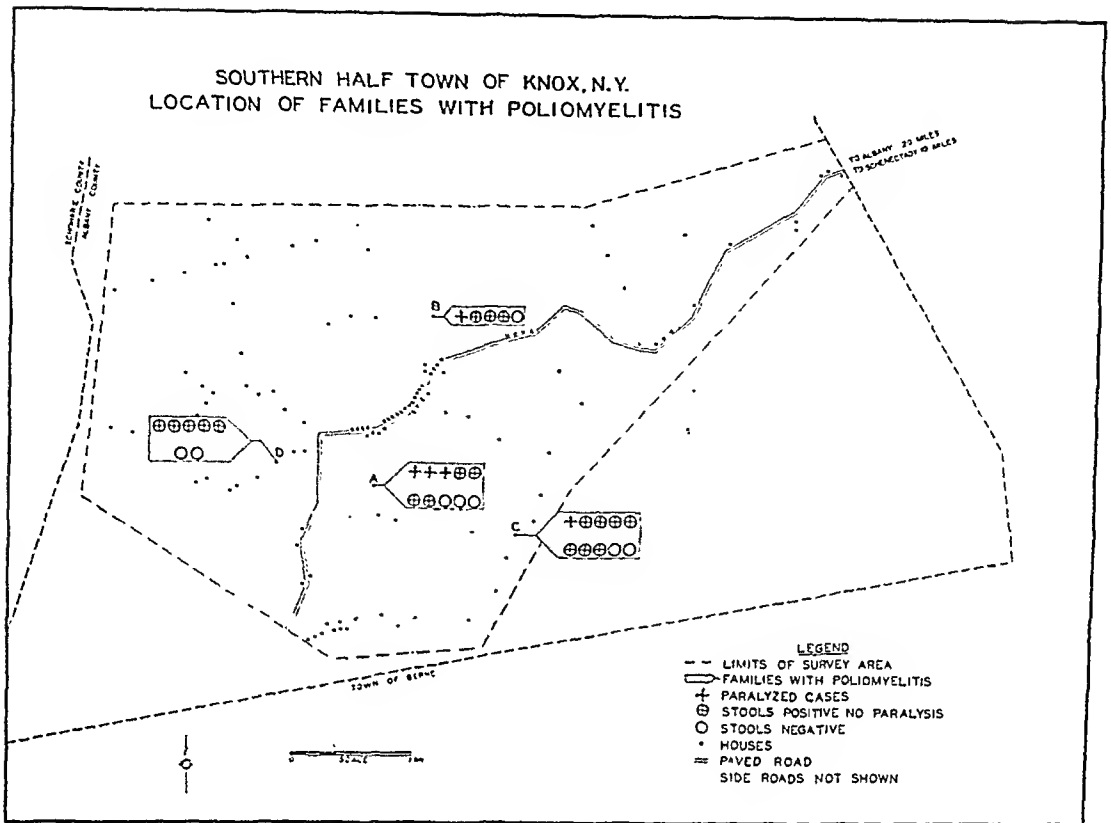

It has been mentioned that 8 specimens were secured from individuals without known contact with any of the paralytic cases. Four of these specimens were from persons in the community who gave histories of previous attacks of poliomyelitis at least 5 years prior to the present outbreak. The 4 other stools were from the members of a family in which 1 child had a febrile illness with vomiting and pain in the abdomen lasting for 2 days. In none of these 8 specimens was the virus found. This group of 8 individuals does not represent a fair sample of the community at large, but the consistently negative results do serve as a check on the validity of the laboratory methods used.

SOURCE OF INFECTION

The chronological and geographical concentration of cases suggests that some unusual characteristics might be discovered in the community or in the activities of the 4 families in which poliomyelitis occurred. The accompanying map shows the location of these 4 families A, B, C, and D, and the distribution of the homes in the area.

Each of the 4 families maintains its own cow, each has a shallow dug well, unprotected from surface pollution, and each has an unscreened surface privy. Although 3 of these 4 families live in extreme poverty, the total lack of improved sanitary facilities is characteristic of the farms throughout the community.

A majority of the population live by farming. A few individuals commute to Schenectady and a small number of city dwellers maintain summer residences. The community is typical of many marginal farming areas throughout New York State, and is quite similar in its sanitary environment to the rural

areas described by Frost (1913) in his studies on poliomyelitis in Iowa.

Three of the 4 families, A, B, and D, are intimately associated. Families A and B, in which 4 of the 5 paralytic cases occurred, are related. The children in all 3 families are regular playmates. Family A and B held a joint party 8 days prior to the outbreak on the A farm. Two days before their onset, the younger children from the A farm visited over the weekend with both family B and family D.

Family C was acquainted but not closely associated with the other 3 families. However, 9 days prior to the onset of the 1 paralytic case in family C, the patient was exposed at a large family party to a number of relatives from Schenectady and Rotterdam.

Only 2 of the members of the 4 infected families had regular contacts outside of the town. The father in family A drove through Schenectady daily on his way to work as a laborer on a construction gang. However, his stool

specimen was not found to contain virus at the time it was examined. The oldest boy in the same family worked throughout the summer at a tea shop in the hamlet where he had casual contact with residents from Schenectady, Albany, and other areas. His stool was positive. None of the members of family C had known contact with either of these individuals for at least 25 days prior to the outbreak, but they were exposed to a large number of persons resident in an area where poliomyelitis was prevalent.

Although no direct or indirect contact between any of the known cases in Schenectady or Albany and the 4 infected families in Knox was discovered, the general character of the community, and the ready accessibility of large urban areas give ample opportunity for a variety of contacts of which no knowledge could be obtained. Therefore, the means of introduction of the infection into the community is obscure, but several possibilities are evident.

Although the explosiveness of the outbreak suggests a common source, none was discovered. To be sure, 3 of the families A, B, and D, were intimately associated but all the members of these 3 households were not known to have been together at any one time, nor was it found that they all partook of the same water, food, or milk at any time. None of the members of family C had visited at any of the other 3 farms for several months prior to the outbreak. In spite of investigation among the members of all 4 households, no evidence of a common source of infection for all the cases could be obtained.

The possibility of an insect vector as the means of transmission of the disease has been considered. House flies and other common insects were present in abundance throughout the area. There was a moderate prevalence of mosquitoes of both the anopheline and culicine varieties. However, the location of the 4 families on isolated farms surrounding but not within the relatively concentrated area of the hamlet does not favor an insect vector, although this possibility cannot be entirely ruled out.

Consequently, personal contact among intimate friends and members of each family is the most adequate explanation for the known infections within the community. All the members in 3 of the families A, B, and D were closely associated and intimately exposed to at least one of the paralytic cases within 2 days prior to the onset of the outbreak. The 4th family was exposed throughout 1 day to residents in an area where poliomyelitis was prevalent. The higher attack rate for acute minor illnesses among the intimate associates is confirmatory evidence supporting the contact hypothesis.

DISCUSSION

That contacts of cases of poliomyelitis may harbor the virus in their stools has been shown repeatedly by Trask,

Vignec, and Paul (1938); Lepine, Sedallian, and Sautter (1939); and Kramer, Gilliam, and Molner (1939). The present study indicates the extent to which carriers and unrecognized cases may develop among the intimate contacts of paralytic cases in a rural community in which a previous case had not been reported for 19 years. Out of the group of 27 contacts examined, 84.5 per cent of the children under 19 years of age and 50 per cent of the adults were carriers. Half of the contacts remained well. Only one of them had sufficient symptoms to meet commonly accepted criteria for typical abortive poliomyelitis. Thus a variety of symptoms must be considered to be suspicious and of these gastrointestinal symptoms appear to be more suggestive than respiratory. But in this series it has been impossible to differentiate clinically between cases with and without virus in their stools.

Spread of infection through personal contact appears to be the most reasonable hypothesis by which to account for this outbreak. The high proportion of individuals shown to harbor the virus must have offered many opportunities for spread from person to person, both among children and adults. But the finding of virus in the feces by no means implies that the disease was transmitted by water, milk, or food contaminated with such discharges.

The extent to which the infection was present throughout the community was not determined. It may have spread widely without attracting notice, in view of the mildness of the symptoms in the unrecognized cases and the large proportion of carriers observed among the contacts.

Further studies are indicated in which fecal specimens are taken from members of the general population as well as from cases and household contacts. It is reasonable to suppose that such studies would provide laboratory con-

firmation of previously held beliefs as to the wide distribution of poliomyelitis virus during an epidemic, and as to the rôle of unrecognized cases and carriers in its transmission.

New Methods of Hookworm Disease Investigation and Control*

JUSTIN ANDREWS, Sc.D., F.A.P.H.A.

Director, Division of Malaria and Hookworm Service, State Department of Public Health, Atlanta, Ga.

THE studies of Keller, Leathers, and their associates¹ clearly show a marked reduction in the recent incidence and, presumably, in the intensity of hookworm infection in the southern states in contrast to the conditions prevailing in 1910-1914 as revealed by the Rockefeller Sanitary Commission. Nevertheless, hookworm disease remains a source of physical disability and economic handicap in certain parts of several states, and considerable amounts of time and money are currently expended by state and local health agencies in its reduction.

Curiously enough, however, the worldwide researches of the last twenty years on the quantitative aspects of hookworm infection have apparently failed to make an effective impact on state and local health authorities. Indeed, the problem is viewed by them almost without exception as a qualitative one. It is taken for granted that hookworm infection is tantamount to hookworm disease. Egg-positive individuals are discovered by annual flotation surveys of school children. The positives are given, or are urged to take, anthelmintic treatment with little regard to their clinical condition, the relative magnitude of their worm burdens, or the probability of prompt reinfection. The only truly preventive values inci-

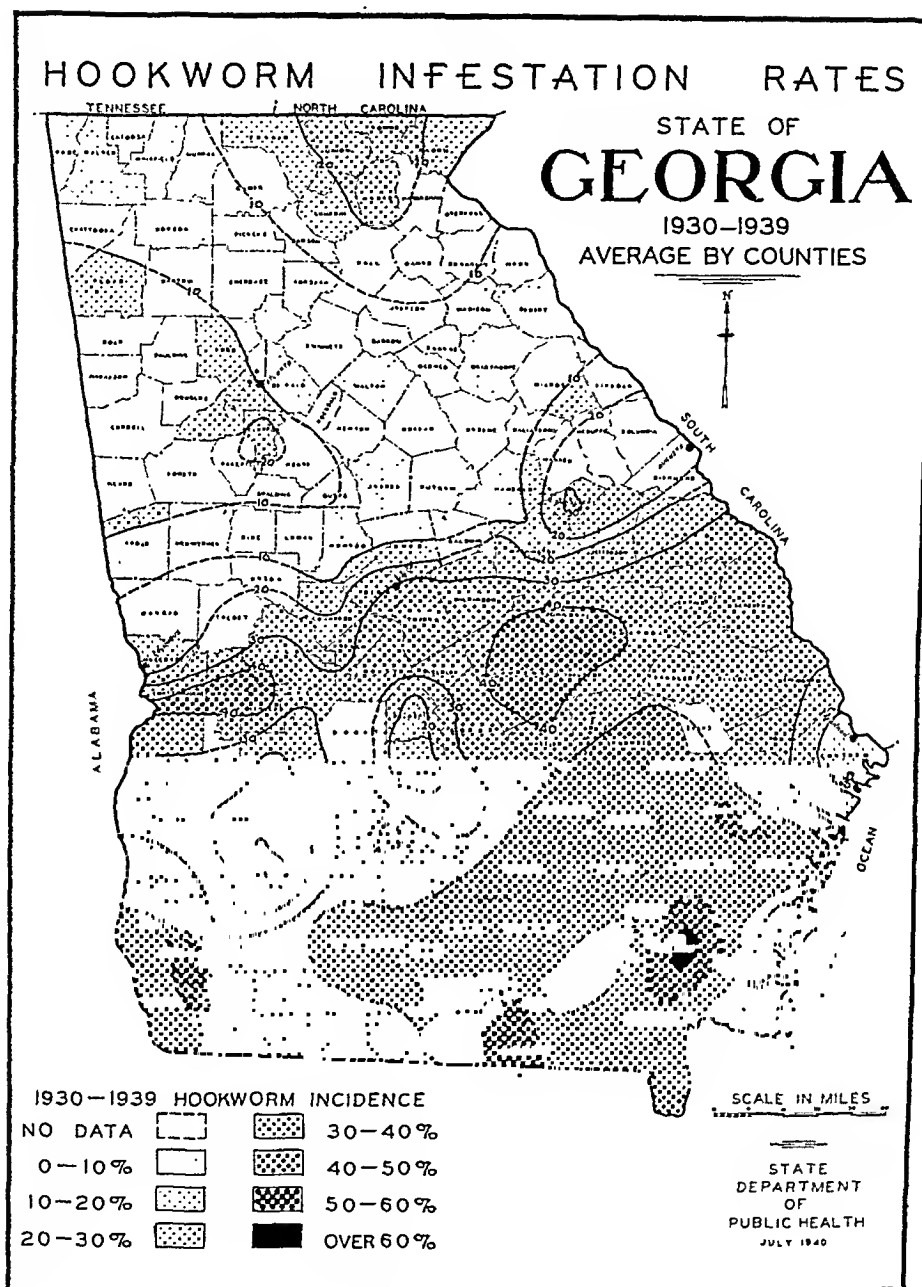

dental to these efforts are when the incidence information is used in the promotion of sanitary excreta disposal facilities at homes and in schools. Thus, these anti-hookworm programs involve the special interests and activities of laboratory, epidemiologic, engineering, nursing, and local health administrative services, but these frequently are not coordinated because the program lacks a guiding plan or specific direction. Much of the work, therefore, is repetitious, unnecessary, and wasteful.

In an attempt to develop a sound anti-hookworm program that could be effectively and conveniently carried on by local health agencies and to assist in its promotion and effectuation in Georgia, the State Department of Public Health established a Hookworm Service unit late in 1939. Personnel includes a nurse and a sanitarian who give their entire time to this project, and a medical epidemiologist and a director (parasitologist) who devote about half their efforts to anti-hookworm activities.

All requests from local lay or health sources for hookworm surveys must be approved by the director before survey materials are supplied. Thus, he is in position to prevent pointless surveys with their wasteful expenditures of time and materials; he frequently can convert the desire to "do something about hookworms" into a more effective procedure than a flotation survey of school children; and, lastly, he can

* Read before the Engineering Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

FIGURE 1

regulate and equalize the laboratory load of hookworm examinations to a very considerable degree.

The first step toward a refinement of existing knowledge of the hookworm problem in Georgia consisted of tabulating, by year and county, the previous 10 years' incidences of hookworm infection as determined by flotation surveys. The county rates for this period were then used in developing an isoropic map (Figure 1) showing the

state-wide distribution of various classes of hookworm incidence. This provided a useful though not statistically or parasitologically ideal basis on which to plan subsequent investigations.

The next step was to substitute, in the minds of local health personnel, quantitative for qualitative concepts regarding hookworm infection. This was done by keynoting the subject at state and regional health meetings and by making it the topic of discussion be-

fore in-service training groups. The following argument was developed.

1. Adult hookworms suck blood continuously, the amount removed being proportional to the number of worms present.
2. If they remove blood more rapidly than it can be formed, hookworm disease, or anemia, results; if not, the condition is one of subclinical hookworm infection.
3. The primary objective of public health authorities should be the detection, prevention, and control of hookworm disease rather than the elimination of subclinical hookworm infection.
4. Inasmuch as the rate of blood removal by hookworms varies directly with the number present and the rate of hemoglobin formation is normally governed by iron and protein intake, it follows that
 - a. Hookworm disease is more likely to occur and will be more severe when worm burdens are high and iron-protein consumption low.
 - b. When adequate iron-protein consumption prevails, hookworm infection, with rare exceptions, will be subclinical, whether worm burdens are heavy or light.²
 - c. When diets are iron-protein deficient, a chronic, progressive anemia will develop irrespective of whether hookworms are present or absent.³
 - d. Even in hookworm infested areas, therefore, all instances of anemia are not necessarily cases of hookworm disease. Intelligently planned hookworm disease control must distinguish between anemias caused or augmented by hookworms and those due to other causes.
5. To accomplish the control of hookworm disease, knowledge of the intensity as well as the incidence of hookworm infection must be available and this must be considered in relation to the apparent anemia and dietary habits of the people concerned.

The third step was the development of a practical program of investigation and control based on this quantitative viewpoint and available epidemiologic knowledge. It was aimed (1) as the destruction of the greatest possible number of hookworms with the least expenditure of time, travel, and materials,

(2) the prompt physical rehabilitation of those sick with hookworm disease, and (3) the prevention of further hookworm infection.

The epidemiologic facts utilized, and their implications, are as follows:

1. Hookworm disease does not occur where approved domestic and school excreta disposal facilities are in use. Thus sanitary sewerage or privied sections generally may be dismissed from consideration.
2. Assuming favorable temperature and moisture conditions, hookworm larvae develop best in sandy or sandy-loam soil.^{4, 5} Strictly clay regions should not be included in the area of examination.
3. Hookworm disease is rarely, if ever, a health problem in Negroes.¹ Thus Negroes may be omitted from investigation.
4. Hookworm disease is predominantly a disease of low-income families. It is, therefore, usually unnecessary to investigate well-to-do families.
5. The findings of Keller and Leathers and their collaborators¹ have focused attention on the family or household group, rather than the individual, as the important unit of hookworm dissemination in the southern United States. Hookworm investigation and control, therefore, should be prosecuted on a family instead of an individual basis.
6. The same investigators have shown that the average individual worm burden tends to increase with the number of infected members in the family. This indicates the greater probability of finding hookworm disease in large rather than small families.

Summarizing the above, it is apparent that, if investigation is restricted to large, white, low-income families living on sandy or sandy-loam soil without sanitary excreta disposal facilities and in which clinical anemia is evident, the majority of the cases of hookworm disease in the area will be encountered.

In apprehending these families, two procedures are in use in Georgia. Where soils, family incomes, races, and domestic sanitation vary widely within a county, direct home visiting without preliminary survey is planned on the basis of soil maps, sanitary survey

maps, and information obtained from welfare agents, county agents, Farm Security representatives, home demonstration agents, physicians, and others whose business takes them into rural homes. Fecal specimens from one or more anemic members of each family, under 20 years of age, are sent to the State Health Department Laboratory and these are examined by brine flotation. Those found positive are egg-counted by the small-drop dilution method of Stoll and Hausheer⁷ to obtain some indication of the relative intensity of infection and the corresponding probability that the anemia observed is due to hookworms.

In counties where sandy soils, poverty, and insanitation predominate, home visiting is deferred until the selective school survey has directed attention to families of probable hookworm significance. This is done by distributing fecal containers only to those white school children who show evidence of being anemic. School teachers are invited to assist in the selection because they are able to make their judgments on the basis of activity as well as appearance and because it gives them definite responsibility in connection with this special health program. These specimens are examined in the State Health Department Laboratories first

FIGURE 2

by flotation to eliminate negatives, the positives being egg-counted.

During the development stages of this program, we urged examination of all members of the suspected families. This turned out to be impractical because of non-coöperation, especially of adult males, and the time and travel consumed in repeated visits to the home. This procedure has been abandoned as we presently discovered that in general

TABLE 1

Comparison of Average Egg-counts per ml. of Formed Stool, by Egg-count Classes, of Initial Family Contacts and All Members of Their Families, Excluding Parents

Hookworm Egg-Count Class	Families, Including Initial Contacts, Excluding Parents						
	Initial Contacts		Number of Members				Average Egg-Count of Positives
	Number Examined	Average Egg-Count	Total	Average	Positive	5,000 or More Eggs per Ml.	
2,000- 4,000	25	2,868	110	4.4	76%	18%	4,692
4,000- 8,000	36	5,419	150	4.2	79%	39%	6,225
8,000- 16,000	28	10,696	104	3.7	92%	60%	9,715
16,000- 30,000	21	22,400	91	4.3	96%	74%	18,607
30,000- 60,000	21	41,181	77	3.7	94%	83%	27,468
60,000-126,000	8	84,550	29	3.6	97%	97%	41,646
Totals	139	18,030	561	4.0	86%	53%	14,080

FIGURE 3

the egg-count of the initial contact, *i.e.*, the first anemic member of the family seen, under 20 years of age, was roughly representative of the average intensity of infection of all positive members of the family under 20 years of age, in which age group most cases of hookworm disease occur in this state. A comparison of average egg-counts of initial contacts and all members of the families is shown for 139 families in Table 1 and Figure 2. Accordingly, we have discontinued routine examination of other members of the family at great saving for both laboratory and local health services.

Similarly, we at first recommended control follow-up of families of anemic individuals with counts of 2,000 or more eggs per ml. of formed stool. This level was selected, more or less arbitrarily, before the results of our own county-wide surveys became available. It allowed a reasonable margin of safety below the egg-count level (2,600 eggs

per ml.) at which Smillie and Augustine⁹ noted minimal symptoms of hookworm disease in Alabama. Our own observations,¹⁰ shown in Figure 3, on the relation between egg-counts and hemoglobin determinations (Sahli) convinced us that it was pointless in Georgia to attempt control in families where the average egg-count was much below 6,000 eggs per ml. This corresponds in Figure 2 to an average egg-count of 5,000 eggs per ml. in initial contacts. Accordingly, local health personnel are now advised to select for control follow-up families of anemic individuals under 20 years of age whose egg-counts are 5,000 or more eggs per ml.

The families selected by either of these methods do not, of course, include *all* the cases of hookworm disease in the area. If faithfully carried out, however, these procedures, with a minimum expenditure of time, travel, and materials, will direct attention to the

bulk of the true hookworm morbidity, excluding that much larger group with hookworms but no hookworm disease. Attempts to eliminate hookworm from the latter group serve no useful health purpose, with the possible exception of promotion, a purpose which should be served better by an actual rather than a fictitious health problem. Nevertheless, knowledge of these families, members of which are suffering from anemia not due to hookworms, is of health significance as it is generally found that these persons are undernourished with respect to iron. Dietary anemia in Georgia, and apparently in Florida as well,³ is more prevalent than hookworm disease with which it frequently and perhaps always occurs. This health problem can be economically attacked along with hookworm disease control; indeed, the two health activities effectively complement each other.

What is to be done for these hookworm diseased families once they are identified? First of all, their sick members must be made well. This requires medical service and, as far as possible, is handled by private physicians in Georgia. Indigency is high, however, among hookworm sufferers and it is usually the expressed desire of local medical groups or practitioners that health doctors assume treatment responsibilities for such patients. Anthelmintic drugs are supplied gratis to medical men by the state.

The therapeutic problem is a dual one consisting of worm removal and treatment of the anemia. As Payne and Payne¹¹ have recently shown, hemoglobin recovery following worm expulsion without iron therapy is a long drawn out process. This is especially true when dietaries are iron deficient.¹⁰ On the other hand, while iron administration alone produces rapid improvement in the blood picture, the gains are not sustained unless the worms are removed. So we do both, giving iron,

usually as Bland's pills, *before* deworming if the anemia is exceptionally severe, *i.e.*, 5 gm. or less; *after* worm removal if the anemia is moderate. Educational efforts are made, thereafter, to improve the dietary so that greater iron intake in food is provided, especially for growing children in which the concurrence of hookworm anemia and nutritional anemia is most marked.

The prevention of hookworm disease is, first of all, a matter of sanitation, *i.e.*, the provision of approved excreta disposal facilities, second, education concerning their use and the physical benefits that will result therefrom and, probably, of improved dietary as well if the immunity hypothesis of Cort and Otto² based on observations of experimental dog hookworm infection is verified in man.

We, therefore, vigorously promote the sale and use of sanitary sewage disposal structures in homes and schools, but in these days of progressively restricted WPA participation in community sanitation projects, of increasing cost and decreasing availability of materials and of labor, the prospects of seriously interfering with the transmission of hookworms by the use of standard sanitary units are comparatively remote. Families that cannot afford minimal medical service cannot afford pit privies.

In those numerous instances, therefore, in which home sanitation cannot be provided, we are trying to develop definitely preventive values from anthelmintic treatment. As indicated above, individuals suffering from hookworm anemia are treated as fast as they are discovered, irrespective of whether or not the premises are to be sanitized. The deworming of other members of the family at that time is not encouraged. If a pit privy is provided and used, there will be no material increase in the intensity of infection and so family treatment is not necessary.

If, however, the household must get along without sanitary facilities, at least one and desirably two worm-removal treatments are urged for all members of the family during the cold months of the year. The object here is to reduce—and, if possible, to eliminate—the family worm burden at a time when immediate reinfection of its members from each other is less likely than it is during the summer months. The unfavorable effect on non-parasitic stages of hookworms of temperatures below 50° F. has been noted by various observers. Augustine,⁶ working in southern Alabama, was unable to find larvae in polluted soil from the latter part of December into March. Our own findings in south Georgia, incomplete and inconclusive, confirm this observation. Thus it appears that the soil in this area tends to become free from infective larvae during the winter months and the likelihood of reinfection following treatment at this season is correspondingly remote. This seasonal prophylactic effect is enhanced by the fact that it is during the cold months of the year that rural residents wear shoes if they ever wear them at all.

Two treatments with tetrachlorethylene completely remove worms from about 90 per cent of the patients and reduce the group egg output by 99 per cent.¹² If these are given during the winter to all members of families in which hookworm disease has occurred, it seems improbable that hookworm infection could build itself up to clinical

intensities in those families within several years.

This program has not yet experienced the test of time. It is subject to improvement as further field investigations suggest. Nevertheless, we feel that through it we are accomplishing better hookworm control at a lower cost than we did before its development.

Methods of Production and Control of Normal Human Plasma and Serum *

MILTON V. VELDEE, M.D., F.A.P.H.A.

Division of Biologics Control, National Institute of Health, Bethesda, Md.

UNDER certain circumstances clinical conditions occur which demand the prompt restoration of blood volume. Such conditions prevail particularly following shock, hemorrhage, and burns. Both laboratory and clinical investigations have shown that such volume replenishment can be accomplished adequately by whole blood transfusions, or the intravenous administration of either normal human plasma or serum. The widespread use of the last two substances has opened up a new field of biologic production and control. The present discussion is not concerned with the clinical value or use of these products, but rather with the mechanics of production and methods of safeguarding both the donor and the recipient.

SOURCE OF SUPPLY OF THE RAW PRODUCT

Heretofore in the production of biologic preparations containing blood the source of supply has been the horse or some other domesticated animal. This has enabled the producing laboratory to keep its source of supply within the limits of the laboratory itself and without regard to the wishes of the donor. With human plasma or serum such an arrangement is obviously impossible. The producing laboratory is forced to search out the potential donor and by some arrangement,

mutually agreeable to all parties involved, arrange for the contribution of a specified amount of blood. How this can best be accomplished depends in a large measure upon the function of the producing laboratory. If it exists as a charitable or community enterprise, it can obtain donors in the following ways:

1. Volunteer donors who come as friends of the laboratory or the community. Such a donor service can best be maintained if it is incorporated into the program of one or more public spirited organizations as, for example, the Red Cross, American Legion, church organizations, Community Chest, lodge, or one of the Service clubs.

2. Volunteer donors provided by the patient from members of his family or friends. In order to give the patient prompt treatment he is treated with material drawn from the reserve supply. The bleedings which he provides in return are contributed later on schedule at the laboratory and these serve to replenish the reserve stock on hand.

A laboratory which obtains its supply of blood through such volunteer services must either have an adequate independent budget to meet its operating costs or must charge each recipient a service fee. Those who cannot afford to pay such a fee should be required to make payment in the form of a specified number of additional donors whenever possible.

As will be stressed later, the operation of a human blood processing laboratory is an exacting task and requires ade-

* Read before the Laboratory Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

quate equipment and well trained, full-time personnel who are responsible only to the director of the laboratory. In order to operate on a sound economic basis, the laboratory must serve a certain minimum territory. Because of these essential requirements, it may be more expedient for a community or hospital to contract with a qualified private laboratory for the processing and control testing on a unit basis. This can be accomplished only if the community or hospital is prepared to furnish the raw product either with or without charge. Economically, such an arrangement is probably less of a burden since the minimum trained personnel and the minimum equipment needed to process even a single unit can process many times the minimum by full utilization of its facilities. There is also the advantage that a privately operated laboratory can ignore institutional and political boundary limitations. An aggressive laboratory director can, therefore, range farther afield and render service to several communities or institutions and proportionately reduce the processing cost per unit. Under such a scheme the financial arrangement between the processing laboratory and each participating unit can be: (a) the raw product plus a unit price for processing with all of the finished product returned to the community of its origin; or (b) the raw product plus a sufficient added amount of the raw product which the processing laboratory shall be free to process and sell in the open market. The latter arrangement will take care of the community which is economically poor, but which can, on the basis of civic interest, obtain bleedings from its members.

There still remains a demand which cannot be met by either of the above plans. This consists of the scattered demand from individual sources which for one reason or another are not eligible for one of the above mentioned supplies.

Providing such a supply is the logical function of a private laboratory. It must buy the whole blood needed for processing for cash from individuals who are willing to sell their blood for a price. The extent to which such a laboratory can operate is limited since no community can supply much blood beyond its own needs and under present operating conditions no laboratory is permitted to go very far afield for its raw supply.

MINIMUM REQUIREMENTS FOR BLOOD PRODUCTS

Irrespective of the method of procuring the raw supply, the physical requirements for the donor, the method of taking the blood, and the operation of the processing laboratory must meet certain very definite standards. Laboratories operating entirely within the borders of a single state need only comply with the state regulations. On the other hand, if the operations become interstate in character, the processing becomes subject to the federal Biologics Act since human blood plasma and serum are by definition biologics. Because of the potential dangers both to the donor and recipient, the U. S. Public Health Service has recognized the need of surrounding the processing of human blood products with very specific restrictions. It is sufficient for this discussion to itemize the points covered by these minimum requirements¹:

1. The donor must be in such physical condition that the taking of 500 ml. of blood will not endanger his health.

2. The donor must be free from any disease transmissible by blood transfusion.

3. The bleeding must be done in an adequately equipped bleeding center which shall at the time be under the control of the licensed laboratory.

4. The bleeding shall be under the immediate supervision of a qualified doctor of medicine, assisted by the necessary trained personnel.

5. The bleeding and all the subsequent steps

involving the blood fraction, until it is injected into the recipient, must be carried out in a closed system.

6. The drawn blood must be placed at 5° C. within 1 hour of bleeding, must be freed of its cells within 72 hours, and if the plasma or serum is to be held in the frozen state or be desiccated, it must be brought to the frozen state within 72 hours.

7. The product from a minimum of 8 bleedings must be pooled and well mixed before filling the final containers in order to dilute the iso-agglutinins adequately and also to equalize the protein content.

8. The product must be sterile as determined by sterility tests made: (a) on the plasma or serum from each individual bleeding or from a sample withdrawn from the pool before the addition of the preservative, and (b) on a specified number of finished containers. Animal safety tests are also made.

9. If the final product is retained in the liquid or the frozen state, it must be placed in a container made of good quality glass, stoppered with a collar type rubber stopper which will permit the entrance of the necessary needles or trochar for administration to the recipient, and the container must be properly labeled.

10. If the final product is processed to the dried state, the finished product must contain not more than 1 per cent of moisture as determined by drying over P_2O_5 , the container must be flame sealed or its equivalent under vacuum in a container of good quality glass and so constructed as to permit the vacuum to draw the diluent into the container, thereby permitting solution of the dried product from the vacuum state.

11. Explicit instructions for the solution of the dried product and for the administration of the liquid material should accompany each package. The user should also be cautioned against overheating the product before administration and also as to the imperative need of using a filter in the lumen of the tube leading to the recipient's vein for the removal of particles dangerous for transfusion.

12. There are other refinements in technic of preparation, assembling, and administration which are being observed by the various producing laboratories. These are not included in the minimum requirements, but do add to the quality of the product and to the simplification of the administration.

serum is to be processed depends primarily upon the degree of stabilization of the component parts desired, upon the storage facilities available, and upon the interval likely to elapse before use.

1. *Liquid plasma or serum*—The preparation of liquid plasma or serum is the most economical both as to equipment needs and production time. Neither preparation is entirely stable since denaturation of the proteins gradually takes place when the product is held in the liquid state. The dissolved fibrin in freshly prepared plasma gradually precipitates with aging, giving serum plus a fibrin clot which must be filtered out before introduction into the recipient's blood stream. The precipitation of the fibrin may be greatly delayed by adding 10 per cent of dextrose to the plasma and avoiding storage at low temperatures. Serum may be stored at 2 to 5° C., whereas plasma should be stored at 15 to 30° C. Where production is for local consumption, and where administration is planned within 1 year, liquid plasma or serum is suitable. On the basis of production costs it is the product of choice.

2. *Frozen plasma or serum*—It has been shown that plasma or serum can be reduced by quick shell freezing to the frozen state without causing any significant alteration in the physical or chemical characteristics of the component parts. Similarly, if it is returned to the liquid state by rapid melting at 37° C., little, if any, change results. Quick shell freezing requires little additional equipment, but does require continuous storage at -5 to -20° C. Production and storage costs are only slightly more than for the liquid product, whereas the frozen product has the advantage of a longer period of usability without denaturation. The full length of this period has not been determined but in all probability it exceeds the 5 year dating period now

PHYSICAL CONDITION OF THE FINAL PRODUCT

The degree to which the plasma or

allowed dried plasma or serum. If low temperature (-5 to -20° C.) shipping facilities are available the frozen product may be shipped to distant points without harm.

3. *Dried plasma or serum*—Removal of the water content from plasma or serum by quick shell freezing and drying from the frozen state causes little physical or chemical change in the constituents. Studies which have extended over several years have shown that if the product is satisfactorily dried and sealed under vacuum in a good quality glass container, further changes in the composition of the dried plasma or serum do not take place. This permits a very long dating period, probably greatly beyond the 5 year dating period now allowed. In addition, since the temperature requirements for storage of the dried material are not limited as with the frozen or liquid product, it may be shipped to remote places and used under circumstances which otherwise would be impossible. It becomes the product of choice on shipboard, in remote regions of the world, and in case of widespread emergency where reserves must be kept under uncontrolled storage for indefinite periods. However, because added processing steps are involved, the unit cost is greater. Simplification of the processing equipment now generally used can be made, and freeing the processing from questionable overhead charges will undoubtedly result in reducing the unit cost to a point where dried plasma or serum may well become the product of choice for all purposes.

The chief problem involved in preparing the dried plasma or serum is the removal of the water without causing significant changes in the physical or chemical composition of the various component parts and without change in their physiological properties. Experience has shown that this involves the application of certain well under-

stood basic laws of physics and chemistry.

It is of interest to follow the historical development of the application of these laws to the desiccation of biological substances. Knowledge of the mechanical phases of desiccation may be said to begin when d'Arsonval² gave his report on the practical production of liquid air in 1898. In 1901, he made his report on the use of low temperatures as a valuable aid in research methods.³ He recommended the use of methyl chloride in order to reach -60° C., solid carbon dioxide or acetylene dissolved in acetone for temperatures of -112° C., or even -115° C., and finally liquid air in petroleum ether for temperatures below -115° C. Silvered vessels with double walls enclosing a vacuum were used. Vansteenberghe⁴ in 1903 applied vacuum over sulfuric acid without regard to the temperature for the removal of water from tissues. In 1906 d'Arsonval and Bordas⁵ used two glass receptacles connected by a T tube equipped with a stopcock. Vacuum was obtained with an ordinary pump attached to one arm of the tube. One receptacle served as the drying chamber and was heated by immersing in water at, for example, 15° C. The other receptacle served as the condenser and was refrigerated by plunging into liquid air or simply into carbon dioxide snow mixed with acetone. They regulated the temperature of the drying chamber to meet the requirements of the substance under analysis. In 1909, Shackell⁶ dried from the frozen state and observed that organic substances dried in this manner with the aid of vacuum and a chemical desiccant retained their physical condition better than when dried at temperatures above freezing. In 1935, Elser, Thomas, and Steffen⁷ reported on the accumulated work of the senior author which he states began in 1909. Elser's contribution was the introduction

of the manifold which permitted the connection of many individual containers of frozen material to the condensing chamber. He also contributed the technic of storing the dried material *in vacuo*. A comprehensive analytical study of the physical phenomena involved in the process of drying from the frozen state was reported by Greaves and Adair,⁸ in 1939.

It is also of historical interest to observe what substances have been desiccated by the technics just described. Brown and Escombe,⁹ in 1898, exposed germinating seeds to liquid air temperatures of -183° to -192° C. and Thiselton-Dyer,¹⁰ in 1900, exposed them to liquid hydrogen temperatures of -250° C. to -252° C. The seeds remained viable. Macfayden and Rowland,¹¹ in 1900, exposed 10 different bacteria, one yeast and raw milk to liquid air temperatures (-183° to -192° C.) for a period of 7 days without an apparent loss of viability of the microorganisms. Vansteenbergh,⁴ in 1903, desiccated rabies virus infected rabbit brain at room temperature and found it viable and fully virulent 9 months later. In 1906 d'Arsonval and Bordas⁵ dried a variety of non-viable organic substances without causing any change in the substances. Shackell,⁶ in 1909, successfully dried from the frozen state a wide variety of foods and other organic substances, including immune hog cholera serum, the serum of guinea pigs, and fresh uncoagulated dog's blood. Except for the loss of moisture, he was unable to note any change in the substances. Harris and Shackell,¹² in 1911, dried whole rabbit brains and cords from rabies virus infected animals by the Shackell method and the virus was shown to remain infective for at least 4 months. Hammer,¹³ in 1911, successfully dried bacteria by the Shackell method of desiccation from the frozen state.

From this historical review of the lit-

erature it will be seen that the physical laws essential to desiccation from the frozen state, as we understand it today, were made known and their applicability demonstrated prior to 1912. More recent reports have merely served to confirm the earlier work and to offer refinements in the mechanics of applying these laws to the problem of desiccation.

This discussion would not be complete without mention of the work of Cohn¹⁴ with the serum albumin fraction from human blood. Physical and chemical studies of this fraction, physiological studies of its behavior in laboratory animals, and a limited number of therapeutic trials in humans indicates its usefulness where the problem is one of restoration of blood volume. Serum albumin can be readily precipitated out of plasma or blood with ethanol-water mixtures to whatever degree of purity is desired. It possesses a very high osmotic pressure, has a low viscosity index, and is readily soluble in water. The aqueous solution readily passes through antibacterial filters, and the finished product remains clear and unchanged even under adverse conditions of storage. Assuming that adequate clinical trials confirm the present opinion of its therapeutic usefulness, serum albumin may well replace whole plasma or serum in those instances where the problem is one of restoration and maintenance of blood volume.

Three Posters

IN the advertising profession the word "standout" is used to describe the exceptional or the meritorious. If the advertising gentry were to judge three venereal disease posters just released by the U. S. Public Health Service, there is no question that these would be termed "standout posters." The posters to which we refer deal with prostitution, blood tests for syphilis, and home remedies for gonorrhea. These are difficult subjects to depict in poster technic and only through skillful interpretation can they be presented for public display.

The Public Health Service has used precisely the right approach to these subjects, and the result is a series of posters that are distinguished on many counts. The most striking feature of each is the elaborate, though highly effective, use of color, and the terse text which can be read at a glance. These posters should be widely used, as their forceful messages need to reach many segments of our population at present.

Statistical Work in the Health Department*

FORREST E. LINDER, PH.D.

Technical Expert, Division of Vital Statistics, Washington, D. C.

A GREAT many papers have been written and read about the statistical needs of a health department. Much less attention has been given to the problems of actually achieving these objectives and the relative success or failure of the present methods of vital statistics organization in doing so.

Briefly stated, an effective public health organization needs two types of statistical information and service. One includes all that is usually given the name of "vital statistics," whereas the other pertains to the analysis of other types of public health and medical data. With vital statistics are included data about the death rate and the birth rate, the age, sex, and racial distribution of deaths, the causes of death, the proportion of births and deaths which have received hospital care, and all the other vast amount of information which can be obtained from the tabulation and study of birth and death certificates. But the health department needs also the other important type of statistical work. Medicine has passed from the realm of art to that of quantitative science, and to an ever greater degree every aspect of the public health program is being tied to a numerical appraisal of its value and efficiency. In addition to the study of vital statistics, the public health administrator is constantly asking for a statistical and

quantitative answer to endless questions, such as: Do the laboratory technics used in the various state laboratories give comparable results? What does the recent survey show about the dental condition of our school children? What data are there to evaluate the success of maternal and child hygiene work? How extensive is venereal disease and how can the progress of the prevention and cure program be evaluated?

These two types of statistical work in the health department are not intrinsically different; they are merely based on data collected in different ways. And a great deal of value of the records of a health department is obtained by studies of the interrelations among data collected from such different sources. For example, upon careful analysis the records of the Division of Vital Statistics yield valuable information. Similarly analyzed, the records of the Infant and Maternal Hygiene Service are of value. However, additional information of perhaps equal or greater value can be obtained by relating these two sets of independently collected data.

If the statistical needs of a health department are visualized in this broad way, it is apparent that from their historical beginnings the state departments of public health in the United States have had an unparalleled opportunity to achieve a high standard of statistical accomplishment. From the early days of American public health work, most state public health offices have had complete control over the collection, tabulation, and analysis of those most impor-

* Read before the American Association of Registration Executives and the Vital Statistics Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

tant statistical documents — the birth and death certificates. The state health department has had the golden opportunity to develop around these basic vital statistics data a well founded and comprehensive organization for the quantitative study of public health problems and progress.

The unique possibilities of the American system of organization become clearer when it is compared with that of other nations of the Western Hemisphere. In most South American nations, a system for the registration of births and deaths has been long established. However, the principal, almost sole, purpose of this registration system has been to record and preserve the facts of birth and death for their legal value. For this reason, the civil register and the public health office are two completely separate and distinct organizations. As a result, the rapidly growing public health organizations of the other American republics find themselves without the basic mortality and natality data which they need for their work. Having no sources of their own, they are dependent upon what they can get from a civil registration organization which is not appreciative of public health needs nor equipped to supply the service and data for which the public health office has a legitimate use.

In the United States, not all states have taken full advantage of the possibilities of the typical American plan under which the registration of births and deaths is a part of the public health organization. Some states perform a high quality of work in respect to both the objectives of legal registration and in the utilization and analysis of vital statistics for public health purposes. However, it is not an exaggeration to state that, whatever are the *potential* advantages of our present system of vital statistics, in many areas of the country this present system is facing imminent breakdown and failure.

Vital statistics has been an integral part of public health for two main reasons. In the first place, it was believed that the health organization would be a proper and efficient organization to develop and administer registration for its legal purposes. Secondly, it was recognized that a good public health program required the data which could be obtained from a study of the registered documents. It is now apparent that these two objectives are not being generally attained. Recent fast moving developments in the field of vital statistics show that the vital statisticians of this country face serious problems of organization.

It is no secret that registration in this country is not complete. This is particularly true for birth registration. The reason is obvious. For years the problems of registration have been the "step-child" of the health department. Many health officers, considering registration as extraneous to public health administration, have given little attention or support to efforts to complete and perfect registration. In many instances state officials have been reluctant to enforce registration laws, and no champion has appeared to fight the battle for adequate appropriations for this purpose. As a result, literally millions and millions of American-born citizens now find themselves without any documentary proof of the facts of their birth. And this is now acutely apparent at a time when such proof is of greatest importance for national defense employment, and a hundred and one other purposes.

This underregistration is now having another result which, from the interests of public health, is equally serious. The need for birth certificates has swamped the state offices with requests for certified copies. Many of the 60,000,000 Americans whose births were not originally registered, are flooding the state vital statistics offices with applications

for delayed filing. Each week, the Bureau of the Census is receiving increasing thousands of requests for age certification from Census records. This experience is paralleled in almost every state office. Many state vital statistics offices are now facing a work-load that they are not prepared to meet. To help solve the problem, special clerks are being hired and assigned to the work. During the past several years an incredible amount of WPA funds has been poured into state and city offices in an attempt to complete and bring up-to-date indexes and files of certificates. Only recently the Bureau of the Census has obtained over a million dollars to be spent within 6 months for state help on delayed registration. But the serious point is that all this represents a diversion of money and time from the analytical work of vital statistics. In almost every state this analytical work is being delayed and neglected. Some states have stopped completely the tabulation of vital statistics.

The opportunity to achieve a comprehensive, well integrated public health statistical office is vanishing. The objective of complete registration has not been attained, and many public health administrators now find their vital statistics office to be nothing more than an enormous filing cabinet, rather than a valuable organization to assist in the quantitative study of public health.

A partial solution to these difficulties may possibly be found in a reshuffling or reorganization of the statistical work within the health department. No uniform pattern for a statistical organization is followed by all states. Some states have made special provisions to meet the dual needs of registration and analysis, but many follow the usual pattern of a central vital statistics office with modifications depending upon the present need for analysis, the available personnel, and other resources. The existing kinds of organizations may be

grouped into four general types. It is worth while to examine each of these types of statistical organizations and to consider its possible efficiency in reference to the analytical and registration work with which we are concerned.

One type of statistical organization might be called the decentralized system. Under this plan there is no one central statistical office for the whole health department; each different division provides its own statistician. Each division develops its own forms, tables, and methods of analysis. Perhaps it even has its own installation of tabulation equipment. It is obvious that this plan is possible only in a large health department where the different divisions have sufficient statistical work to justify a separate statistical service for each.

Several state public health offices have this plan of independent statistical units, and in New York State, for example, the decentralized plan is quite feasible. In New York State, the Division of Vital Statistics works in collaboration with the statisticians of other divisions, and there is a ready exchange of basic data. But the statisticians employed by the various subject-matter divisions are not administratively responsible to any one chief. A certain amount of integration of work and methods is accomplished by seminars and interdivisional conferences, but the system is definitely decentralized. Although the Division of Vital Statistics carries on extensive analytical research, this research is confined largely to the analysis of vital statistics data.

The statistical service that had been established in Tennessee is exactly opposite in type. In this state, the statistical service is not decentralized but is very definitely concentrated in one central office, which is almost an integral part of the office of the Director of Public Health. The statistical office is a service unit for all of the regular operating divisions of the department.

An important aspect of this plan is that the analytical work on vital statistics, which in most states is done in the registrar's office, has also been taken over by the central statistical service. The Division of Vital Statistics is concerned primarily with problems of registration, filing, corrections, certified copies, and some routine coding. The statistical work is definitely separated from registration work.

Another plan for a centralized statistical service is to be found in the State of Alabama. In this state the analysis of mortality and natality data is not taken out of the Division of Vital Statistics. On the contrary, the analysis of other public health statistics is carried on as a regular function of that division. The regular work of the state registrar is not, therefore, limited to registration problems; it includes the rather extensive statistical analysis of vital statistics data as published in the annual Alabama reports, and also a variety of tabulations and studies for other health department divisions. This service work to other divisions means that the Division of Vital Statistics supplies these divisions with special tabulations of vital statistical data, consults with them on coding, tabulating, and analytical problems, and makes special tabulations of their own data for them. The Division of Vital Statistics also controls the central installation of tabulating equipment and acts as a service unit to administrative statistics.

A new type of organization is now being developed in Louisiana. As a part of a general plan for the reorganization of the state government and the Department of Public Health, there has been created a new Division of Public Health Statistics. Concentrated into one administrative unit are all the functions of collecting, tabulating, and analyzing for the whole health department. That the functions and duties of this division are more extensive than those relating

to births and deaths is indicated by the fact that the name of this division is the Division of Public Health Statistics, not the Division of Vital Statistics.

This new division is divided into three main sections—one for registration, one for tabulation, and one for analysis. But the section for registration embraces more than the registration of births and deaths. Included also are morbidity registration and the collection of other kinds of data needed for the health program. Similarly, the sections for tabulation and analysis extend their functions to all other public health statistical problems. In this type of organization, vital statistics in its traditional sense has been superseded by a larger and more comprehensive statistical organization.

To the extent that these organizational plans make provision for public health statistical work and also separate and independent provisions for registration work, they may help solve the basic conflict which now exists between these two competing vital statistics activities. But as long as the total funds are limited, there still remains the basic problem of finding some way to keep the ever-increasing load of registration from overshadowing and smothering the equally important analytical work.

It is not the purpose of this paper to suggest a solution to this dilemma. It is intended here only to present the problem and attempt to stimulate discussion among registrars and public health officials regarding possible methods both to improve registration and to advance the work of the statistical analysis of public health problems.

Perhaps in some states, a reorganization giving more emphasis to vital statistics and an increase in available funds will suffice. However, perhaps the time has now come for a more fundamental change in the vital statistics system. One solution would be for the public health system to give up the responsi-

bility for registration. Following the South American pattern, a state civil registration system could be set up which would be entirely independent of the state health offices. The public health statistical office would then be free to concentrate on the interpretation, publication, and distribution of factual data. Some New England states have always operated in this way. The real importance of the birth and death certificates in the administration of a public health program is the most forceful argument against this complete separation of registration and public health statistics.

Another possibility is for the state public health offices to concentrate on the problems of registration and to discontinue the tabulation and analysis of vital statistics. The statistical data of some other organization, such as the Bureau of the Census, could then be used by the state health offices. This

suggestion is perhaps the most unsatisfactory of all because no one would claim that the Bureau of the Census publications can ever be completely adequate for the current administration needs of a health office, nor can they be designed in sufficient detail or in a way to fit the needs of each different state.

The optimum solution is probably neither of these, but some other which combines the advantages of all. Some method must be found that can keep the basic vital statistics data close to, and available for the use of, local and state public health offices. At the same time, some relief must be given the state vital statistics offices in the heavy and responsible work of registration. These offices must be permitted to become truly statistical offices, with the time and facilities to play their full part in the quantitative study, planning and evaluation of the problems and success of the state public health program.

Chorio-Allantoic Membrane Infection as a Diagnostic Test for Smallpox*

S. W. BOHLS, M.D., F.A.P.H.A., AND J. V. IRONS, Sc.D.

Division of Laboratories, State Department of Public Health, Austin, Tex.

SEVERAL laboratory tests for smallpox have been devised; these may be classified as "infective" or serological. Schultz, Bullock, and Lawrence¹ and others obtained unsatisfactory results with complement-fixation in the diagnosis of smallpox but Craigie and Wishart² and others have been more successful. Craigie and Wishart² found that complement-fixation was somewhat more sensitive than the flocculation reaction. Of the "infective" tests, the Paul test, which is performed on the rabbit's eye, was employed by Scott and Simon³ with success. Both Toomey and Gammel⁴ and Defries and McKinnon⁵ were somewhat less successful, while Jorge⁶ and others obtained unsatisfactory results. Defries and McKinnon⁵ advocated the difference in dermal response of susceptible and vaccinated rabbits as the basis for a laboratory diagnostic test. With rare exceptions, none of these tests has been reported to give "positive" findings in chicken pox. Each of these tests has failed to win wide acceptance in the United States.

Following the fundamental observations of Woodruff and Goodpasture⁷ with the fowlpox virus, several of the pox viruses were propagated in the chorio-allantois of the developing fertile hen egg. Both Buddingh⁸ and

Irons and his associates⁹ suggested that chorio-allantoic infection might have value as a diagnostic test for smallpox. Irons, Bohls, and Hartman¹⁰ found the chorio-allantois was more susceptible than the rabbit's cornea to variolation. Since health officers sometimes desire laboratory aid in dealing with mild, sporadic cases of possible smallpox or with fulminating chicken pox, we have given more attention to the chorio-allantoic infection test.

THE MANIPULATION OF EGGS

A satisfactory source of fertile eggs is a prerequisite. Eggs may be incubated successfully in the bacteriological incubator if a large pan of water is added to increase the relative humidity and other details are given attention. Eggs are likely not to do well in hot summer weather. We have employed essentially the window technic of Goodpasture and Buddingh,¹¹ which permits ready inspection of the chorio-allantois at any time. Since cutting the egg shells with file or carborundum pencil was rather tedious, we employed a modified dental drill, consisting of a reversible motor with foot pedal control and a flexible shaft, driving a slip clutch handpiece. A candling device enables one to check viability and location of the embryo and attached membranes. Windows were constructed by removing a section of shell flap approximately 1 cm. square over the larger blood vessels

* Read before the Laboratory Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

and by the substitution of a coverslip over a wax base. This operation requires some skill and attention to good technic in order to avoid excessive bleeding by puncturing the membranes. Eggs with windows should be handled with care to avoid adhesion of the cover glass to the membrane. For excision or final detailed examination of the chorio-allantoic membranes, the top of the egg is made bare by cutting around the window.

COLLECTION OF SPECIMENS

Consideration was given dermal lesions rather than blood specimens and throat or nasal swabs. Since sensitivity of the test depends very much on the collection of ample and satisfactory specimens, it is fortunate that the physician is likely to visit the patient when the lesions are rich in virus content. We recommend the avoidance of facial lesions and those elsewhere which have been broken by scratching or rubbing, since these are prone to be mixed with staphylococcal infections or contaminations. Several virgin pustules should be carefully cleaned and rubbed dry with alcohol and their contents should be aspirated individually or in small pools and transferred to sterile moist tubes; the tubes may contain a small amount of sterile, neutral glycerin. The specimens should be properly sealed and rushed to the laboratory, preferably on dry ice or in a cold box. Crusts are likely to be less satisfactory, but should be requested in the absence of semi-fluid contents.

INOCULATION OF EGGS

Several suitable eggs should be employed in each test. Rapid tests for bacteria enable one to use the specimens to best advantage; occasionally it is advisable to request the collection of additional and more suitable specimens. Selected specimens

should be triturated or resuspended in a small amount of sterile saline diluent, and a few drops of inocula should be dropped through the windows of eggs on uninjured membranes. One should avoid opening windows longer than is necessary. The use of saline diluent tends to retard excessive dehydration and promotes spreading the inoculum over the membranal surface. The eggs should be incubated at a temperature of 35°–36° C. and should be inspected carefully once or more daily.

DESCRIPTION OF LESIONS OF EXPERIMENTAL SMALLPOX IN PRESUMPTIVE

POSITIVE TEST

These descriptive data on experimental smallpox apply to bacteria-free lesions in eggs incubated 10–14 days at time of inoculation. Contaminated or mixed lesions were subject to great variations and frequently resulted in early embryonic death. In the presumptive positive test, the minute lesions were rarely detected in less than 24 hours. The character of the lesions depended somewhat upon the severity of the infection on the membrane. Considerable variations occurred in the number of pocks which appeared, even in the several membranes inoculated with the same material. If 10 to 100 pocks appeared, these usually reached a maximum diameter of about 1 mm. in 72 hours. When a heavier infection with crowding occurred, the average diameter of the pocks was somewhat less; peripheral pocks oftentimes were larger. In about 30 hours the pocks were invariably clearly visible, although scarcely more than pinpoint in size, as watery, raised, rounded, discrete spots. These lesions resembled those in actual smallpox and seemed to evolve through the classical stages of the smallpox lesion, but the whole process was much speeded up and in miniature. As

a rule, individuality of the pocks was well retained until the 4th or 5th day when coalescence occurred, giving rise in the heaviest infections to creamy areas of pustulation, or, in lighter infections, to more rapid formation of areas of desiccating, necrotic tissue. These necrotic plaques were cast off when the chick hatched. The evolution of the lesions, with each of the 18 isolates which we obtained from patients with smallpox, has followed along essentially the same pattern, which was characteristically rather different from what we have observed with influenza, vaccinia, herpes and certain other viruses, bacteria, and fungi. Contents of pustules have given better results than crusts; failures have been much more frequent with the latter.

generally can be attached to the presumptive positive test. To confirm and complete the presumptive positive test, the following criteria have been utilized: (1) increase in number of pocks by sub-inoculation, (2) demonstration of histological picture consistent with smallpox, (3) demonstration of elementary bodies, and (4) significant diminution in pock count under the influence of antivaccinal serum. Not all of these criteria are required for every test.

ATTEMPTED SMALLPOX PASSAGE IN EGGS

At the first indication of smallpox lesions in eggs, and concurrently with sterility and other tests to exclude possible bacterial and related infections, one should attempt to transfer the infection to other egg membranes.

THE COMPLETED POSITIVE TEST

We have generally avoided reporting definite evidence of smallpox until the test was completed; although, as we have gained in experience we have come to believe that much importance

Nearly always in experimental smallpox we have found an increased number of pocks at the first transfer, as shown in Table 1. Each of 18 isolates was carried through several egg passages. Hen egg propagated smallpox was also

successfully transferred on chorio-allantoic membranes of pheasant, duck, turkey, and goose eggs.

HISTOLOGICAL FINDINGS IN EXPERIMENTAL SMALLPOX

Histologically, the well defined foci, corresponding with the visible lesions, and consisting of cellular proliferation, inflammation and necrosis, were invariably outstanding. While all three embryonic layers were often involved, the entoderm was attacked to a lesser extent. The ectodermal cells were particularly involved and these suffered the most pronounced necrotic effects. The mesoderm was edematous in the involved areas and, as the changes progressed, contained an increased number of inflammatory cells which scarcely tended to wander into the entodermal areas. Where necrotic changes were not too pronounced, and particularly in the more involved lesions, intracytoplasmic inclusion bodies were frequently seen in the ectodermal cells. These acidophilic structures varied somewhat in size and shape and were characteristic of the classical Guarnieri bodies. Guarnieri bodies were not found in every focal lesion and particularly with respect to the milder infections.

DEMONSTRATION OF ELEMENTARY BODIES

In carefully prepared films from smallpox lesions, which were stained by the Morosow¹² method, it was usually possible to demonstrate moderate numbers of elementary bodies. The technic was controlled by the use of both uninfected and vaccine infected membranes. In lightly infected membranes one should be sure that an actual pock is spread on the slide. In employing the Morosow or similar technic, careful attention must be given the details to avoid the appearance of ruinous precipitates. Large numbers of evenly distributed elementary bod-

ies, which are commonly found in vaccine films, were seldom encountered in smallpox films.

EFFECT OF HYPERIMMUNE, ANTIVACCINIAL RABBIT SERUM ON POCK COUNTS

Hyperimmune, antivaccinial rabbit serum should exert a protective effect against not only vaccinia but also to a lesser extent against smallpox. We have employed two moderately potent antivaccinial sera with controls in repeated tests with smallpox virus on egg membranes. It was usually possible to obtain a definite reduction in pock count which could be attributed to the influence of antiserum, although the results were subject to considerable variation. Pocks which appeared in the presence of antivaccinial serum tended to be only slightly smaller or delayed in appearance in comparison with controls. Normal rabbit serum and saline diluent respectively mixed in equal amounts with decimal, supernatant virus suspension constituted the controls. Mixtures were left in the cold room at a temperature of 4°-8° C. overnight and a total of 0.4 ml. was pipetted after gentle agitation to each of a dozen eggs in each test.

NEGATIVE FINDINGS

In the presumptive negative test at least 4 embryos should be viable after 48 hours, none of which bear possible chorio-allantoic smallpox or other lesions. In this connection one must be thoroughly familiar with nonspecific changes. Sterile ulcers are most likely to occur in membranes of the younger embryos, and particularly at sites of trauma. Mild surface irregularities may occur as a result of excessive dehydration or for other reasons. The negative finding is completed if the sub-inoculation of pooled, triturated, sterile membranes results in failure to detect smallpox lesions in a satisfactory

group of egg membranes. The completed negative report should be available ordinarily in 96 hours.

ATTEMPTED REPRODUCTION OF CHICKEN POX LESIONS

On numerous occasions we are able to obtain satisfactory specimens from cases of chicken pox. Excepting a couple of clinically doubtful cases, neither of which had been vaccinated and from which the smallpox virus was obtained, the inoculation of chicken pox specimens invariably has failed to elicit the appearance of detectable lesions of the chorio-allantois. Attempted membrane passages, on the assumption that initial reactions might be inapparent, have also given completely negative results and we failed to obtain specific histological changes consistent with those in chicken pox. It seems evident enough that the hypothetical chicken pox virus is unable to affect the chorio-allantois in a visible manner.

PROPAGATION OF HERPES VIRUS IN CHORIO-ALLANTOIS

Dawson¹³ and others have described the development of herpetic lesions in the chorio-allantois of embryonated eggs. On several occasions we have infected the chorio-allantois with blister fluid from herpetic lesions, and under standard culture conditions these infections have behaved much alike. By careful daily observation it was evident that herpetic lesions tended to develop somewhat differently from those of smallpox, although it must be admitted that the lesions were occasionally somewhat similar. However, herpetic blisters tended to be smaller, more superficial and irregular, and proportionately somewhat less edematous and short-lived than smallpox lesions. Intracellular inclusion bodies consistent with those in herpes were also demonstrated. The appearance of herpetic

blisters was not significantly influenced by antivaccinal sera.

ATTEMPTED REPRODUCTION OF LESIONS IN MISCELLANEOUS CONDITIONS

We failed to obtain specific chorio-allantoic lesions with blood and dermal lesions from 3 cases of measles. Rake and his associates¹⁴ apparently have propagated the measles virus in embryonated eggs, but the variable, sporadic lesions which these workers have described could hardly be confused with those of smallpox. We also failed to effect chorio-allantoic alterations by means of material from a case of herpes zoster. Dermal preparations in a few instances of drug rashes and likewise from syphilitic conditions failed to elicit specific chorio-allantoic lesions. Staphylococcal infections were encountered frequently in this series but streptococcal or mycotic infections were seen much less often.

DISCUSSION

From 18 of 27 cases of smallpox, characteristic smallpox lesions were reproduced in the chorio-allantois of embryonated hen eggs. Failures were more often encountered in advanced cases where desiccation was most marked. The lesions obtainable in experimental smallpox of the chorio-allantois were applicable in a rapid presumptive diagnosis of smallpox. Standard procedures have been described and the necessity of following standard methods has been stressed in the early recognition of chorio-allantoic lesions. This test involves the reproduction of specific lesions in the absence of bacterial or other agents; in this respect, the goal is pure culture of the smallpox virus. The technic of chorio-allantoic culture is not difficult to master but its application to the diagnosis of smallpox may give disappointing results in the hands of the uninitiated.

Although our experience indicates

that the presumptive positive test ordinarily may be readily confirmed, the completed test should not be neglected and certainly should be performed whenever a doubtful situation arises. Unless quite satisfactory specimens are employed by an experienced worker, a negative outcome should be given only minor consideration in the exclusion of smallpox and should never be allowed as an excuse for neglecting vaccination.

In submitting specimens for a laboratory test, the physician should not relax his efforts at careful clinical observation. The evidence should be considered in the light both from the laboratory test and from careful investigation. In the performance of this test, as in much laboratory work, a disadvantage is attached to dependence upon submission of satisfactory specimens. In our experience, the physician is very anxious for helpful suggestions and appreciates a suitable collection outfit to aid in obtaining satisfactory specimens. It is possible that the sensitivity of this test may be extended by the laboratory application of methods tending to destroy bacteria in the frequently contaminated crusts, or by other refinements of technic.

Our findings corroborate those of Burnet and Lush,¹⁵ Buddingh,⁸ and others concerning the apparent insusceptibility of the chorio-allantois to the chicken pox virus and those of Bohls and Irons¹⁶ regarding the practical utilization of chorio-allantoic infection in the embryonated hen egg as a diagnostic aid in suspected smallpox.

SUMMARY AND CONCLUSIONS

Eighteen isolates of smallpox virus were propagated in the chorio-allantois of embryonated hen eggs in an environment free from bacteria and fungi. Characteristic lesions, which were consistent with those of smallpox, appeared

in less than 48 hours and were applicable in the laboratory diagnosis of smallpox.

The presumptive positive result was available usually on the 3rd day. Four days were required for the completed negative test. Final identification of the lesions required the application of additional cultural, microscopic, histological, or serological methods.

Tests with chicken pox specimens gave negative results. The chorio-allantoic infection test should be carefully applied in the light of clinical findings and a negative outcome should not result in withholding vaccination against smallpox.

Rheumatic Fever Reportable in California

ACCORDING to *Western Public Health* the California State Department of Health has made rheumatic fever reportable by physicians.

"Conjunctivitis Spread Checked in Shipyards"

"An epidemic of acute kerato conjunctivitis which has affected over 500 employees in shipbuilding establishments in the San Francisco Bay area is being investigated by the Bureau of Epidemiology, Laboratories, and Influenza Research of the California State Department of Health and the Industrial Hygiene Service.

"A department bulletin states that the condition is evidently infectious in origin but that laboratory examinations of smears and cultures obtained from

the eyes of workers have so far failed to identify the causative organism. Animal inoculations have been made to determine whether a virus is responsible for the conjunctivitis.

"Control measures which have been adopted by plant officials upon the recommendation of the State Health Department, including segregation of affected employees, establishment of separate examination and treatment rooms, crews, and equipment for eye cases; thorough sterilization of welding goggles, helmets, and other personal protective equipment; and careful personal hygiene to prevent transmission of the infection from one worker to another, have resulted in a rapid decrease in the number of new cases."

Studies on Syphilis in the Eastern Health District of Baltimore City*

III. Study of the Prevalence of Syphilis Based on Specific Age Groups of an Enumerated Population†

E. GURNEY CLARK, M.D., M.P.H., AND
THOMAS B. TURNER, M.D., F.A.P.H.A.

Associate in Venereal Diseases; and Professor of Bacteriology, In Charge of the Subdivision of Venereal Diseases †; School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

ACCURATE measurement of the trend of syphilis is difficult because of certain inherent characteristics of the disease itself and because of factors of selection which frequently operate in studies of incidence and prevalence. For the past five years studies have been conducted in the Eastern Health District of Baltimore City in an effort to evaluate existing methods for the measurement of this trend.^{1, 2} A resumé of the problems frequently encountered in prevalence and incidence studies has recently been made by one of us (T.B.T.).³

In a disease such as syphilis the operation of an attack rate over a period of years results in an accumulation of persons with syphilitic infection and syphilitic disease of varying degree. Data on this accumulation of past and present syphilitics, defined as prevalence in these studies, are not easy to assemble, for it is necessary to know not only the number of persons in any group that shows evidence of syphilis

(i.e., a positive serologic test or characteristic lesions) at the time of the study but also those who have ever shown such evidence in the past.

A study of the extent of this accumulation in the Eastern Health District was initiated in 1939 because of the availability of certain data on the general population of the district. During that year this population was enumerated according to age, sex, color, and certain social-economic factors by the Department of Biostatistics in cooperation with the Baltimore City Health Department.⁴ From these records the names of all Negro residents of the ages 20-24 years and 35-39 years were chosen for study.

The age group 35-39 was selected, first, because other studies in the District¹ and elsewhere⁵ indicate that the attack rate of syphilis among colored persons of this age group is very low and consequently few persons not already infected will become so after age 35; second, while in a certain proportion of persons with syphilis spontaneous reversal of serologic tests is believed to occur, a minimum of such reversals has probably taken place at these ages. Prevalence rates, therefore, should be at or near their peak.

The ages 20-24 were selected because

* Read before the Epidemiology Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 15, 1941.

† From the Syphilis Study of the School of Hygiene and Public Health, The Johns Hopkins University.

‡ This study was supported by a grant from the International Health Division of the Rockefeller Foundation.

the prevalence rates among these persons should reflect the operation of an attack rate in the recent past and thus give an indication of the problem of early syphilis in the area under consideration.

It should be emphasized that these groups are entirely unselected as regards syphilis. While prevalence rates for syphilis based on these groups are not truly representative of the District population as a whole, they may be used as one index of the situation regarding the disease in this community. Moreover, the rates for the same age groups from year to year should accurately reflect the trend of the disease in the District.

METHOD

The area of study consisted of two wards in Eastern Baltimore with a total population of 57,042, 24 per cent of which is Negro. The study group comprised 2,395 Negroes, 17.8 per cent of the entire colored population. There were 467 males and 651 females of ages 20-24, and 646 males and 631 females of ages 35-39.

The name, age, address, hospitals attended, and other pertinent data on every person in these four groups were obtained from the census records of the Department of Biostatistics, and a card was made for each individual. Each card was then checked against our own department syphilis status master file of some 35,000 names of Eastern Health District residents¹ and against the records of various hospitals, clinics, and laboratories in the city in order to disclose any recorded evidence as to the syphilis status of the individual as of 1939. After existing records had been thoroughly searched, a visit was made in an attempt to locate each person on whom no data had been found in order to persuade each one to submit to an examination for syphilis. In order to establish absolute minimum rates, very

rigid criteria were used in classification. A person was considered "syphilitic" on the basis of definite diagnostic data; a positive serologic test, a definite history of specific treatment for syphilis, or written records of previously positive serologic tests. For a "non-syphilitic" classification, a negative serologic status did not suffice unless it was accompanied by entirely negative history and physical examination. A person whose status was unknown as of 1939 but who was known to be negative prior to 1939 or found positive since 1939 was classified as "no data" along with those on whom there was actually no information available.

The first classification as regards syphilis status was made therefore on the basis of these very rigid criteria, and the prevalence rates, when computed on the total number of persons in the group, are absolute minimum figures. It is possible, however, to establish a closer approximation to the actual prevalence rates by making certain corrections. These corrections were made for subsequent classifications and are discussed below.

RESULTS

At the close of the period allotted for the study some information relative to syphilis had been obtained on approximately 80 per cent of the entire group. On the basis of these data all persons in the study could be placed in one of the three categories: (1) those found to have or have had syphilis, (2) those who were non-syphilitic, and (3) those on whom no data were obtained. Syphilis prevalence rates were calculated not on the basis of examined persons only but on the basis of all members of the original groups.

Prevalence rates according to age and sex—In Table 1 are shown the prevalence rates for all persons in the two age groups studied. These rates are computed in terms of the *known* syphilis

TABLE 1

Syphilis Status of Negroes Aged 20-24 Years and 35-39 Years in the Eastern Health District 1939

(Definitely Known Syphilis Status Only)

	Age 20-24						Age 35-39					
	Male		Female		Total		Male		Female		Total	
	Num- ber	Per cent	Num- ber	Per cent	Num- ber	Per cent	Num- ber	Per cent	Num- ber	Per cent	Num- ber	Per cent
Syphilitic	92	19.7	204	31.3	296	26.5	217	33.6	255	40.4	472	37.0
Non-syphilitic	272	58.4	346	53.2	618	55.3	252	38.9	248	39.3	500	39.2
No data	103	22.9	101	15.5	204	18.2	177	27.5	128	20.3	305	23.9
Total	467	100.0	651	100.0	1,118	100.0	646	100.0	631	100.0	1,277	100.1

status in 1939, and represent the absolute minimum of syphilis infection in each group. In the 20-24 year groups the female rate is 50 per cent higher than that for the males, 31.3 per cent as compared with 19.7 per cent. This order of magnitude was expected because as a rule females are infected earlier than males. The degree of magnitude, however, is startling because it indicates that almost one-third of all Negro females and one-fifth of all Negro males in this area are infected with syphilis before they reach 25 years of age. In the older groups a minimum of 33.6 per cent of the males and 40.4 per cent of the females were syphilitic. The older female rate is approximately 20 per cent higher than that for the males, but this difference is within chance variation. It is possible that the ultimate prevalence of syphilis is approximately the same in the two sexes, the male infection being acquired at

later ages than that of the females. The rate for males increases by 70 per cent between the ages of 25 and 40 and that for females only 29 per cent. It should be pointed out here that any actual or estimated number of syphilitics in the "no data" group will increase the syphilis rates. This is taken into account in a later table.

Prevalence rates according to various social and economic factors

Marital status—Table 2 shows the prevalence rates according to marital status. Among single persons of the ages 20-24 the rates for females, 36.4 per cent is twice that for males, 18.6 per cent. The proportion of unknowns was almost identical in the two groups. In each age group the rates for married males were approximately the same as those for single males. The rates for those previously married were higher than either but the differences were not statistically significant. The rates for

TABLE 2

Syphilis Prevalence Rates According to Marital Status of Negroes Aged 20-24 Years and 35-39 Years, Eastern Health District 1939

	Age 20-24				Age 35-39			
	Male		Female		Male		Female	
	Number	Per cent Syphilitic	Number	Per cent Syphilitic	Number	Per cent Syphilitic	Number	Per cent Syphilitic
Single	269	18.6	242	36.4	169	31.2	46	54.4
Married	162	19.1	327	24.5	440	31.8	401	36.2
Previously married	36	30.5	82	43.9	97	44.3	184	46.2
Total	467	19.7	651	31.3	646	33.6	631	40.4

single Negro females in both age groups were significantly higher than those for married ones, but did not differ appreciably from the rates observed among those who had previously been married.

Education—Approximately 9 per cent of the older group had attended high school, whereas 24 per cent of the younger group received at least this much schooling. The prevalence rates among those who reached high school or beyond were generally lower than those among persons with less education. However, only in the younger group were the differences statistically significant. These results may be a reflection of the educational campaign directed to the venereal diseases during the past few years.

Employment status—In all groups the rates among the unemployed were higher than among those regularly employed but the differences were within sampling variation.

*Social economic classification**—The group classifications used for the purpose of this study were: (1) skilled and semi-skilled, (2) laborers and no usual occupation, and (3) the servant class. The rates observed according to this classification reflected the rates of the specific age and sex groups themselves and no statistically significant differences could be demonstrated with respect to social-economic classes within the specific groups.

ESTIMATION OF CORRECTED TOTAL SYPHILIS RATE

In all the prevalence rates given above the "no data" group has been considered as entirely non-syphilitic, and the rates have been based on the number of known syphilitics in the total population of the respective age groups.

Obviously this is not the true situation, since almost certainly there were some cases of syphilis among the "no data" group. While no information regarding syphilis is available on the individuals comprising the "no data" group, data are available which will permit an estimate of the proportion of syphilitics and non-syphilitics in this group. When such an estimate is made, an inclusive prevalence rate for the entire age group may be computed.

In order to estimate the number of cases of syphilis in the "no data" group, two corrections have been made. First, there are a number of persons in the group on whom some evidence regarding the presence or absence of syphilis is available, although this evidence does not satisfy the rigid requirements set forth at the outset. For example, in the 35-39 year age group there are 19 persons known to have a negative syphilis status after they had reached the age of 30 years, although no examination had been made during or subsequent to 1939. Since the annual discovery rates for early syphilis in this community are known to be low for Negroes between 30 and 39 years of age (7.0 per 1,000 for males and 2.6 per 1,000 for females)¹ it seems reasonable to assume that nearly all of these persons remained free of syphilis during the few years subsequent to the recorded examination. For the same reason, the 26 persons of this age group who were found to have latent syphilis in 1940 or the first half of 1941 may be considered to have been syphilitic during 1939. In computing the corrected rates, then, the status of both of these groups has been changed from unknown to known.

The second correction was made on the basis of prevalence rates among known groups believed to be relatively homogeneous, with respect to the prevalence of syphilis, with the "no data" group. In order to make this correc-

* Classified according to *Alphabetical Index of Occupation by Industries and Social Economic Groups*, U. S. Dept. of Commerce, Bureau of Census, 1937.

tion the entire study group was reclassified according to the type of information on which the syphilis status was based, as follows: (1) those on whom data were supplied by existing records, (2) those on whom data were obtained by subsequent examination, and (3) those on whom no information at all was available. In Table 3 the prevalence rates for classes 1 and 2, are given and the first correction noted above has been made in the "unknown" class.

per cent of the males and 56.8 per cent of the females had been so diagnosed.

On the other hand, the prevalence rates among those on whom there were no existing medical records but who were persuaded to submit to an examination, Class 2 were much lower, being for age 20-24, males 10.8 per cent and females 18.2 per cent; for ages 35-39, males 27.6 per cent and females 34.2 per cent. As far as can be determined the only variable factor between Classes

TABLE 3

Prevalence Rates Based on Existing and Subsequently Obtained Data on Negroes Aged 20-24 Years and 35-39 Years, Eastern Health District 1939

(Includes Both Known and Probable Syphilis Status)

Class	Age 20-24				Age 35-39				Total	
	Male		Female		Male		Female		Total	
	Per cent		Per cent		Per cent		Per cent		Per cent	
	Num- ber	Syphi- litic	Num- ber	Syphi- litic	Num- ber	Syphi- litic	Num- ber	Syphi- litic	Num- ber	Syphi- litic
1 Data from existing records	201	38.1	366	48.1	300	60.4	382	56.8	1,249	52.2
2 Data obtained subsequently	166	10.8	192	18.2	192	27.6	143	34.2	693	22.4
3 No data obtained	100	?	93	?	154	?	106	?	453	?
Total	467	20.3	651	34.0	646	36.2	631	42.0	2,395	33.2

It is obvious that groups for which data existed and those for which no data were obtained are not comparable because the former comprise persons who seek medical care, many of whom seek it for syphilis itself. This is reflected in the high rates for Class 1. Among the 20-24 age groups 38.1 per cent of the males and 48.1 per cent of the females had been diagnosed as syphilitic, and among the 35-39 ages, 60.4

2 and 3 is that members of the former Class were persuaded to report for examination while those of Class 3 were not. In respect to marital status, duration of residence in the Eastern Health District, employment, education, and other socio-economic factors, the two classes appeared to be homogeneous. It seemed a reasonable procedure, therefore, to apply the rates for each age and sex of Class 2 to the corresponding

TABLE 4

Estimate of the Total Prevalence Rate for Syphilis Among Negroes Aged 20-24 Years and 35-39 Years, Eastern Health District 1939

	Age 20-24						Age 35-39					
	Male		Female		Total		Male		Female		Total	
	Per cent		Per cent		Per cent		Per cent		Per cent		Per cent	
	Num- ber	Per cent	Num- ber	Per cent	Num- ber	Per cent	Num- ber	Per cent	Num- ber	Per cent	Num- ber	Per cent
Syphilitic	106	22.7	228	35.0	334	29.9	276	42.7	302	47.8	578	45.3
Non-syphilitic	361	77.3	423	65.0	784	70.1	370	57.3	329	52.2	699	54.7
Total	467	100.0	651	100.0	1,118	100.0	646	100.0	631	100.0	1,277	100.0

members of Class 3 in order to obtain an estimate of the number of syphilitics "expected" among the unknowns. These "expected" numbers were added to the number of known syphilitics and new prevalence rates were computed. These rates are given in Table 4 and are higher than those of Table 1 for reasons previously given. The final corrected syphilis prevalence rates for the 20-24 age groups are males 22.7 per cent and females 35.0 per cent; for the 35-39 age group males 42.7 per cent and females 47.8 per cent.

DISCUSSION

In prevalence studies on syphilis the accuracy of the results depends largely on two factors. The first factor is related to the selection of the group to be studied, for it should be chosen without reference to syphilis. The second factor is the manner of selection of the individuals within the chosen groups. Practically, this means that the number of persons on whom no information is available should be relatively small and that there should be some rational method of estimating the prevalence rate among them. Moreover, the accuracy of a study is further enhanced by the inclusion of those who have shown evidence of syphilis in the past as well as those who present evidence at the time of the study.

These favorable factors obtained to a degree in the present study, for an attempt was made to secure information on all persons belonging in one of two groups, selected solely on the basis of race and age. Definite data regarding syphilis were obtained on about 80 per cent of these persons and information was available which made it possible to estimate the prevalence of syphilis among the remainder.

These principles have been embodied to a varying degree in previous studies of this nature. In a review of their own and other studies Maxcy and

Brumfield⁶ point out the limitations of serologic surveys in estimating prevalence as well as the limitation of surveys of treatment agencies and hospitals. They studied a sample comprising 40 per cent of the Negro population of Albemarle County, Va., but excluded patients examined at the University Hospital, jail inmates, and court cases. In those studies rates were based on the proportion of positives among those tested and no attempt was made to apply rates to the unknown groups, nor to inquire as to the previous syphilis status of those whose tests were negative.

Roberts and Williams⁷ approached the matter in a somewhat similar way by applying to the unknown group the rates obtained in a random sample of a non-clinic population. However, in determining the age specific rates, clinic registrants were omitted from the analysis.

In most of these studies based on serologic surveys, a declining rate after age 35 was observed. This has been attributed to one or more of the following factors: reversal of serologic test to negative with or without treatment, a higher death rate among syphilitics, and a previously operating lower attack rate. The rates obtained in the present study, based on serologic testing and history, are from 25 to 50 per cent higher in the 35-39 age group than in the ages 20-24 among both males and females. It was not possible from this material to determine what proportion of the syphilitics had experienced serologic reversal. However, the latest test in 13 per cent of the young syphilitic group and 16 per cent of the older was negative.

SUMMARY

1. From an enumerated population, all Negroes aged 20-24 years and 35-39 years, were selected for study, and an attempt was made to determine the syphilis status of each.

2. From a study of existing records and from examinations made during the course of the study, minimum prevalence rates were established. These rates are as follows: ages 20-24, males 19.7 per cent, females 31.6 per cent; ages 35-39, males 33.6 per cent and females 40.4 per cent.

3. Among females of both age groups the rate for single persons was higher than for the married. The highest rate recorded was 54.4 per cent among single Negro females 35-39. The rates for males, married and single, were approximately the same within each age group.

4. Rates determined according to educational status were slightly higher among those who had not attended high school.

5. The rates were slightly higher among those unemployed than among the regularly employed.

6. The rates among skilled and semi-skilled workers were about the same as those among laborers. The servant class in all except the young males had higher rates than laborers.

7. Of the three groups, (1) existing data found, (2) examined subsequently, and (3) no data obtained, the latter two were quite similar in composition. Consequently the rates of class 2 were applied to class 3 for a final estimate of prevalence which was: ages 20-24, males 22.7 per cent, females 35.0 per cent; ages 35-39 males 42.7 per cent and females 47.8 per cent. These rates take into account the known syphilis status and the probable syphilis status of those examined, and the expected syphilis status of those not examined.

8. It is believed that the method of study employed here is susceptible of application in subsequent years, and that the prevalence

rates so obtained will afford a reliable index of the trend of syphilis in this community.

ACKNOWLEDGEMENT--The authors wish to express appreciation for the coöperation of Dr. Huntington Williams, Commissioner of Health of Baltimore City, and of Dr. C. Howe Eller, Director of the Eastern Health District. They also wish to acknowledge the assistance of Dr. G. F. Badger of the Department of Biostatistics, who made available for the study certain data from the files of that department. In addition they wish to express appreciation for the coöperation of the Negro physicians in the Eastern Health District.

IN DEFENSE OF SQUARE PEGS IN ROUND HOLES

IT is inevitable that strong and far-flung corps of amateur strategists arise whenever there are rumors of war, or war. This on the whole is probably a very good thing. It tends to maintain public interest and public morale. It creates a sort of loyal opposition to whatever is being done. It encourages map study and, of no small importance, it whiles away the time of those not immediately engaged in more productive occupations. It would be disastrous, of course, if these easy-chair and cracker-barrel plans were put to the test, and to prevent this God has wisely forbidden that the disposition of the fleet or the allocation of lend lease material should ever depend upon the decisions of those uninformed as to the whole problem and untrained in military strategy.

Because of this divine prohibition, then, it is quite safe at luncheon, temporarily to take military matters entirely out of the hands of General Marshall, and it does no harm to shift submarines and destroyers from the Atlantic to the Pacific and vice versa. But those in the medical profession and in professions complementary to it are not so far removed from the affairs of the medical corps of the services as the ordinary layman is from military strategy. Physicians are the ones who are or will be serving as strategists and tacticians in military medicine, and their criticisms of the way in which the medical services are being expanded do not always fall upon as sterile ground as does the vehemence of amateur strategists in general. One physician is influenced by the opinion of another and, unless one knows at least as much of all the problems and facts as do the Surgeons General and their staffs, it is probably not wise to take the responsibility for shaping the thoughts and actions of other physicians and the public.

Particularly harmful is the recounting of stories that imply distressing stupidity in the assignment of medical officers to duty. One hears of the plastic surgeon assigned to the examination of recruits, the laboratory man serving as regimental surgeon, the trained public health man performing sick call duty, of large numbers of medical officers twiddling their thumbs. Perhaps these things have occurred: it would be strange in so rapid a service expansion if they did not; and their occurrence would undoubtedly be distressing and discouraging to the particular

officers concerned. But does anyone imagine, if and when such things happen, that those responsible do not know they are undesirable, or imagine that every effort is not being made to prevent and correct them? One on the outside who criticises the placement of square pegs in round holes should be sure that there are not more round holes and square pegs than there are square holes and round pegs. Even if this is not the case the critic should be certain that round holes are not, at this time, a more serious problem than square ones; and he should withhold his criticism unless he is quite sure that it is better to leave round holes unfilled than it is to fill them partially with square pegs. In sounding off about medical officers not fully occupied, would the critic be willing to assume responsibility for not developing immediately, in view of future needs, a medical corps larger than is necessary to meet today's demands?

We for our part feel that these criticisms, off the elbow as it were, are to be deprecated. They tend to make physicians reluctant to offer themselves for military service, and when they do go into the medical corps, as many of them must, they may enter upon their duties with a lack of faith in their superiors. And finally, to reach decisions when all the facts are not known reflects neither mature judgment nor scientific restraint.

MATERNAL HEALTH AND DIET

FOR a long time there has been need of substantiable data as to the beneficial effects of an adequate and balanced diet during pregnancy. It has been hard to obtain evidence of this sort and, except for sporadic and specialized bits of information here and there, the belief that diet would influence favorably both mother and child has, therefore, rested largely upon observation and general experience rather than upon controlled experiment. In the recent past, however, most encouraging advance in procuring objective findings has been made by Ebbs and his associates in the University of Toronto.

Dr. Ebbs presented a brief report of this work at the 1941 meeting of the American Public Health Association, but the publication rights to this material had been promised elsewhere. His findings, however, are of unusual interest and importance to public health workers, and those who wish to study one of his early reports are referred to the paper, *The Influence of Prenatal Diet on the Mother and Child*, which appeared in the November issue of the *Journal of Nutrition*. We are advised that other aspects of these studies will be presented, from time to time, in appropriate publications.

What Ebbs and his associates have done is essentially this: There were 380 prenatal cases, who had not reached the end of the sixth month of pregnancy, and who presented no major disease. One hundred and seventy appeared to have a reasonably good diet, and this group, designated as the "Good Diet Group," received routine care plus continuing advice as to diet. The other 210 had poor diets. Of these, 90 were provided routine care plus supplementary food necessary to provide a reasonably adequate diet. These were designated as the "Supplemented Diet Group." The remaining 120 cases had routine care but were left to their own devices and resources as to diet, and were designated as the "Poor Diet Group."

Apparently every care was exercised in an attempt to hold constant in the three groups all factors other than diet. Detailed analyses were made of each

patient's food at the beginning of the study, and were repeated two months later. Hemoglobin, vitamin C, and phosphatase were checked by blood examinations, and an obstetrical rating was given each patient in the prenatal period, during labor, and in convalescence. This rating also included condition of baby at birth, ability of mother to nurse the infant, and a rating for the whole course of pregnancy for the time each patient was under observation. Babies were examined at six months and twelve months of age, detailed records being kept. It is of interest, too, that the obstetrical ratings were made by one unfamiliar with the diet group in which patients were carried.

This description, of course, represents only the bare framework of the study. Space does not permit recounting of the various checks and counterchecks utilized to insure accuracy and avoid selection, nor is it possible to present the findings in detail. However, the author's own cautious summary, which is substantiated by tables, is extremely significant: "It would appear from these observations that poor nutrition in expectant mothers results in an increase of anaemia and infection during the prenatal period, in more sepsis and haemorrhage during labour and the puerperium and more complications during convalescence. It would also appear that the improved nutrition of these women has resulted in fewer miscarriages, permatures, stillbirths and deaths during the first months of life. There was a marked difference in the incidence of illness in the babies. This decrease in maternal morbidity, infant morbidity and mortality has resulted in less hospitalization and medical care. Whether future examinations will reveal any changes in the teeth, in physical or mental development will have to await time."

"The results of these observations seem to justify the importance which has been attached to instruction of the expectant mother in matters relating to diet. That many incomes are inadequate for providing proper nutrition is well known. Increased relief rations during pregnancy would appear to be good insurance. The cost of the food sent to the mothers in this study averaged \$25.00 per patient (for four and one-half months)."

Dr. Ebbs' conclusions are as follows: "By supplying certain simple foods to the diets of low-income expectant mothers, the incidence of complications during pregnancy was less and the outcome of the infants up to the age of 6 months was markedly improved."

Here is something definite that public health workers may well explore, both in terms of further investigations and in concrete application in the field.

Credit Lines

A Selective Digest of Diversified Health Interests

D. B. ARMSTRONG, M.D., AND JOHN LENTZ, M.S.

EVERY LITTLE BIT HELPS

In every office where editorial work is done one hears, with increasing frequency, talk of shortages and priorities in the publishing field. That publishers must cope with diminishing paper supplies, or inferior grades of paper, is no longer a remote possibility. There are also reports, presumably well founded, that colored inks will likewise become scarce and that certain metals used in making plates and cuts must be allocated for more vital purposes. These circumstances make it imperative for every agency utilizing printed matter to plan future publications not dependent upon the use of materials upon which the government has first call.

The production of health literature is no small item in the publishing field and the time has come when health agencies should consider ways and means of conserving paper and other publishing necessities. What about the outside back covers of your health pamphlets? An inventory of a large collection of pamphlets from various health agencies reveals that this space is almost never utilized. Why? Perhaps the writers simply ran out of something to say or else the space was left blank for esthetic reasons. It is somewhat strange that this should be true when one considers that outside back covers of magazines are eagerly sought by advertisers who are willing to pay large sums to place their copy in this space. We hereby propose—for the duration—a Society for the Full Utiliza-

tion of Outside Back Covers. Will you join up today?

There are other ways in which we can contribute to the conservation program. Writers of health pamphlets might put themselves on a word-and-space rationing basis. Boil down everything there is to say—"make every word work or fight." Then there is the matter of margins. Although wide margins and white space enhance the appearance of any publication, we can forego these luxuries in the name of war economy. As for color, health publications seldom splurge on this item. Hereafter when tempted to turn out a "two-color job," carefully consider that impulse. Black and white can be used most effectively when mixed with a dash of ingenuity. There is also the question of the size of health publications. "Vest pocket editions" might well be adopted as a uniform size for our literature until materials are again plentiful.

Perhaps we may feel that the restrictions we face will "cramp our style." It is well to remember, however, that circumstances which test one's ingenuity are often blessings in disguise. When put on short rations we may become increasingly skillful in using the tools at our disposal.

AN EDITORIALETTE: INDIFFERENCE— THE DEADLIEST DISEASE OF ALL

For defense or for total war we cannot afford human waste—especially where it is most controllable, namely *in our civil population*. Disease and physical deficiency are wastes of the most destructive kind. To curb and eliminate them is an obvious need in

Please address samples of printed matter, comments, or other editorial contributions to the editors at One Madison Avenue, New York, N. Y.

peacetime; it is a patriotic duty in time of war. Surgeon General Parran has stated that the physical fitness of the people in this emergency "will determine almost entirely the effectiveness of all other defense efforts."

Yet it has been estimated that in our more mature age groups today, probably 70 per cent of the handicap of disease results from functional disorders or premature degenerative conditions that are preventable or readily detectable, or easily controlled or postponed in their incipency. This means an unnecessary burden upon our productivity, and an excessive load on our medical profession—a luxury which we can now ill afford, in view of the impending scarcity of professional services of all kinds.

This appears to reflect a form of negligence or indifference not only by the uninformed and underprivileged, but, more significantly, even by those with the means, the information, and the intelligence necessary to their own assistance. Most Americans, after all, have the facts about disease prevention, or know where readily to secure them.

Perhaps many of us have still to realize the importance of individual health maintenance as a patriotic obligation, especially in this time of stress. Individual health is an asset and a social contribution at all times. Now, more than ever, we owe its enhancement to ourselves and our families, to the conservation of professional resources, to the ultimate conquest of preventable disease, and to the service of our nation at war.

An understanding of the relation of individual health to national vitality will help us to a conquest of Indifference—the Deadliest Disease of All.

(EDITORIAL NOTE: Won't you help us continue this series of "editorialettes"? There must be many subjects in the field of health education upon which you would like to express an opinion. Let us have your thoughts on any of

these subjects. You may praise, criticize, or philosophize—provided it is done in not more than 150 words. While we cannot guarantee publication, serious consideration will be given your contribution.)

RECENT HEALTH PUBLICATIONS

You will want to see. . . .

Trouble in the Midriff, the latest addition (No. 5) to the Workers' Health Series. The U. S. Public Health Service has seldom produced any popular health publications that are as cleverly done as the booklets which make up this series. The most recent booklet designed for the worker deals with "stomach trouble," which "causes 20,000,000 days of lost time yearly." *Trouble in the Midriff* explains the nature of "stomach trouble" and offers sound advice to those who are victims of this "disease" in one form or another. The booklet, like others in the series, is illustrated with amusing sketches, and the light-veined, though informative, copy is a joy to read. Available from the Superintendent of Documents, Washington, D. C.

Cracking Up Under the Strain, a reprint from *Hygeia*, that may now be procured in booklet form from the Bureau of Health and Public Instruction of the American Medical Association, 535 North Dearborn Street, Chicago, Ill. This is a particularly timely publication, since longer hours of labor are now required and the stresses and strains of wartime are increasing. This booklet presents a thoughtful analysis of those factors that often lead man to dig his own grave. Suggested remedies for "the strenuous life" are discussed—remedies that will make for calmness, steadiness, equanimity, and relaxation. Health agencies will probably have use for literature of this type as the population faces more and more of the realities which come to a nation at war.

Single copies of this publication are sold at 10 cents and quantity prices are furnished on request.

First in Your Thoughts, a publication of the Maternity Center Association, 654 Madison Avenue, New York, N. Y. Health agencies are beginning to issue a new type of literature to acquaint the public with measures that must be taken during emergencies. A splendid example of emergency health literature is this leaflet from the Maternity Center Association. "You should be ready to have the baby at home" is the warning sounded in this publication. Articles necessary for the mother and baby, instructions as to how to prepare the bed, facts about labor and the delivery of the child, are among the subjects discussed for the benefit of the layman who may be forced to take over the duties of the nurse or doctor should our normal medical facilities be disrupted. This is exceedingly valuable information which all prospective parents should have—emergency or no emergency. The leaflet is priced at 50 cents per hundred copies.

Health Is No Puzzle, a leaflet issued by the Connecticut State Department of Health. This is a novel presentation of the nutrition problem in which certain essential foods are shown as parts of a jig-saw puzzle. When fitted together, the puzzle forms a daily food picture made up of those nutrients that insure health, vigor, and vitality. This original approach to the subject should prove most effective in teaching children elementary food facts. Address the State Health Department, Hartford, Conn., for copies.

How's Your House? a booklet prepared by the Philadelphia Housing Association, 1717 Sansom Street, Philadelphia, Pa. Here is an effective leaflet that will promote interest among all classes of tenants and owners in "keep-

ing the home fit." Those aspects of housing that are directly related to healthful living—sanitation, cleanliness, lighting, ventilation, and safety—are stressed in this booklet. You will like the illustrations and the text. Write to the above-mentioned organization for copies.

Course of Lessons in Food Selection and Cooking, prepared by the Nutrition Committee of Greater New York, 105 East 22nd Street, Room 200, New York, N. Y. This material is intended for the use of professionally trained nutritionists who teach groups in community nutrition programs. The course outlines points to be covered in six 2 hour lessons. Each lesson includes simple instruction on the nutritive value of a given food, with directions for a cooking demonstration using that food in a meal plan. Recipes for a variety of low cost foods, a reference list for teachers, and a food quiz are also included in the contents. This publication is priced at 15 cents per copy and is well worth it.

Tuberculosis, a new and up-to-date booklet published by the Metropolitan Life Insurance Company, 1 Madison Avenue, New York, N. Y. This publication was prepared in coöperation with the National Tuberculosis Association and the American Trudeau Society. It covers rather completely those aspects of the disease and its treatment about which the general public should be informed. Increased demands for literature on tuberculosis will no doubt be experienced by many agencies in view of recent newspaper publicity regarding the predicted rise in the tuberculosis death rate. The Metropolitan booklet is available without cost.

THREE FILMS

"Hidden Hunger" is the timely title of a new two-reel picture presented by the Federal Security Agency for use in the national nutrition program. As an

educational picture it is somewhat limited in scope, due to the film's short length. "Hidden Hunger" does, however, effectively stress the importance of a wide dissemination of essential nutrition knowledge and the necessity for providing the right foods for all types of people. The theme is developed along somewhat unusual lines, a fantasy approach being utilized. The picture is also well acted by a competent cast, including Walter Brennan, one of Hollywood's leading character actors. From the standpoint of its entertainment value, this picture is better than most films that are now available on the subject of nutrition. "Hidden Hunger" is, at present, for theatrical use only. Communications regarding the picture should be addressed to "Hidden Hunger," Room 401, Graybar Building, New York, N. Y.

The American Social Hygiene Association has released a new one-reel film on gonorrhea entitled, "Health Is a Victory." This is a well balanced presentation in which the facts about gonorrhea—its diagnosis, treatment, and cure—are told in simplified language. Featured in the film are several animations and diagrammatic sketches showing the prevalence of the disease, how it spreads, and how it affects the human organism. Information concerning modern methods of drug treatment and the dangers of self-medication is also stressed. There are no objectionable features to the film and it is particularly well adapted for showing to mixed audiences. "Health Is a Victory" is available in both 16 mm. and 35 mm. prints (for sale or rent) from the American Social Hygiene Association, 1790 Broadway, New York, N. Y.

Under the auspices of the First Aid, Water Safety, and Accident Prevention Service of the National Headquarters of the American Red Cross, a new four-reel film on first aid was recently released. The picture was made in

coöperation with the New York City Chapter, the staff of which appears in the cast. The film is essentially a review of certain standard first aid procedures, including the control of bleeding by digital pressure and tourniquet, methods of administering artificial respiration, transportation of the wounded, the dressing of burns and minor wounds, and other procedures now so widely stressed in first aid programs. This film does an admirable job of presenting in an understandable way many of the more important first aid procedures. Preview audiences voiced the opinion that this film could be used most effectively with students completing first aid courses under an instructor, the picture serving as an actual demonstration of first aid procedures as practised by trained workers. The film may be shown as a whole or in parts. Information concerning prints may be obtained from the Red Cross National Headquarters in Washington, D. C., or from local chapters.

"HEALTH IN A PACKET"

Dr. C.-E. A. Winslow, of the Yale Department of Public Health, once said: "The discovery of popular education as an instrument of preventive medicine . . . has proved as far-reaching in its results as the discovery of the germ theory of disease." Remembering this and, mindful that the health of the entire population, not just the military, is essential to national defense, even in wartime, the Health Education Section of the Council of Social Agencies of Los Angeles last year set out to acquaint the public with available health education material.

This Section, a part of the Health Division of the Council, undertook the task of assembling and effecting the distribution of the best of authoritative information covering the major field of health. The Section, consisting of a carefully selected committee of lay and

professional leaders, gathered samples of printed material, lists of motion pictures, speakers, exhibits, and posters on (1) general health, (2) maternal and child hygiene, (3) social hygiene, (4) mouth hygiene, (5) tuberculosis, and (6) other specific diseases. Individual specialists in the group studied this material and selected the best for inclusion in a large packet called "Your Health." Samples of literature and lists of additional publications, speakers, films, and exhibits were placed in separate 8" by 10" envelopes under the six titles mentioned above. Each subdividing envelope, printed in two colors, carried a line drawing suggesting its contents and a list of the material enclosed.

The educational systems of the community were the most logical channels for distribution. A packet was supplied to the Health Coördinator in each of the high schools of Los Angeles to provide ready reference on material available for health programs in the schools. Since the home plays an equally important rôle in the health education of children, the packets were supplied to the health chairmen of approximately 200 Parent-Teacher Associations in the areas served by the Council of Social Agencies. One health worker remarked after viewing the packet that the Parent-Teacher Associations had in the packet the basis for a five year program on health. Because the Parent-Teacher Associations do not include as many fathers as mothers, the Section made packets available to the health committee chairmen of the major men's service clubs, and special libraries have been given packets for deposit in their reference material on health.

The packets include, in addition to samples, lists and similar material, a simple explanation of where and how pamphlets, films, posters, exhibits, and speakers may be obtained by any group in the community.

Approximately 500 copies each of the

pamphlets included were donated by health and medical agencies and insurance companies.

THREE ANNUAL REPORTS

Annual reports that hold the reader's attention from cover to cover are indeed noteworthy editorial achievements. Such a report comes from the Commonwealth Fund, and if you have not yet read this agency's account of its 1941 activities, we urge you to do so. Here is a purposeful, carefully planned, and skillfully written report that succeeds remarkably well in describing the scope of the agency's work. Of special interest are those sections of the report dealing with the peculiar rural health problems which the Fund staff has done so much to solve. The final section of the report—entitled, "Saturday Morning"—creates a vivid and dramatic picture of the daily work of a county health department. One detects the rare editorial ability of Geddes Smith, of the Fund staff, throughout the 1941 report. It is a most commendable job.

Another unusually good annual report is that of the National Foundation for Infantile Paralysis, Incorporated. A very detailed account of the 1941 program is presented with pertinent facts and figures on all phases of the Foundation's work. It is interesting to note the expansion of the Foundation's educational program, which now includes grants for professional and popular educational materials, including pamphlets, periodicals, and films. This well documented report is neatly arranged, both as to layout and typography.

The Queensboro Tuberculosis and Health Association of Jamaica, N. Y., is to be congratulated on its 1941 report entitled "Three Fourths of the Way." An exceedingly simple, though pleasing, cover and distinctive stylized illustrations set this report apart from the usual run of annual statements. This report also reveals a splendid record of service

in many types of community health work.

JOTTINGS

In a recent issue of "Credit Lines" attention was called to the health exhibits at the Smithsonian Institution in Washington, D. C. It was pointed out that these exhibits have long been on display and that certain of them could probably be improved and modernized. It is good news to learn that something is being done in this direction by the Museum authorities, with the coöperation of the National Health Council and the U. S. Public Health Service. . . . A tip on titles: "An appropriate, interesting title for a health booklet is just as important as a good headline on an advertisement. Perhaps even more so. In the case of the advertisement, the eye may see some of the rest of the message in spite of the headline. But if the booklet title sounds dull and dry, the cover page may never be turned. One important consideration in framing a title is the idea of personalized treatment—getting in the 'you' element. The 'you' headline has won definite acceptance as one of the best approaches in advertisements." . . . Two books you will want to read: (1) *Let There Be Mercy*, by John Maloney, and (2) *This Chemical Age*, by William Haynes. The former relates the experiences of a special observer who visited the war-torn countries of Europe to survey and report upon the tragic conditions found there. This story will make every American proud of the part our Red Cross is playing in alleviating human misery. The latter book recounts the wondrous accomplishments of modern chemistry and shows how this science affects our comfort, health, and safety.

. . . Observations from Reba F. Harris, Associate Director, Bureau of Public Health Education, Kentucky State Department of Health, on films: "Very few health films really meet the needs of rural areas, particularly in the South. Yet we find, I believe, a greater use of such films in the smaller communities. One of my main objections to so many of our health films is that the films have been devoted to diseases, rather than to the total living process of human beings. In other words, we have placed the emphasis on the germ and the transmission of the disease and yet we have not shown the effects of this disease on the family and family living, nor the relationship of this family with this disease to the community in which they live. I think there is a definite need for this type of health film, particularly in the South." . . . Homer N. Calver of the American Museum of Health reports a simple method of making paper charts translucent. To the back cover of unmounted charts, apply melted camphor ice. Press this into the paper or cloth mounting of the chart with an electric iron and wipe off the excess camphor. The chart is thus made translucent, may be mounted between glass, and may be illuminated from behind by fluorescent light. The process is adaptable to all types of charts, though it is recommended that before expensive charts are treated in this manner the paper or cloth of the same type used in the chart be experimentally treated. . . . Responses to the appeal for slogans are still coming in. Dr. Lester Breslow of the Rochester, Minnesota, Health Unit submits the following: "A Healthy Nation Today—A Healthy World Tomorrow."

BOOKS AND REPORTS

The Anaerobic Bacteria and Their Activities in Nature and Disease. (A Subject Bibliography.)—By L. S. McClung and Elizabeth McCoy. *Supplement I Literature for 1938 and 1939.* Berkeley and Los Angeles: University of California Press, 1941. 244 pp. Price, \$3.50.

Two volumes under the above main title first appeared in 1939, presenting approximately 120,000 entries of about 10,500 original journal articles, monographs, and other published reports, for a period of 122 years from 1816 to 1938. Volume I gave a chronological index of authors, a subject index outline with page references to Volume II, and a valuable list of abbreviations used in citing periodical references.

Volume II was arranged by subjects, the main headings being habitat, culture methods, morphology, metabolism, products of metabolism, physiology, serological studies, disease relation, classifications, and special lists, each of these being again subdivided for chronological listing. Each reference gave the author's name, his initials, the journal, volume, inclusive paging, and year, but not the title, making it necessary to refer back to Volume I to find the title of each article. This made the use of the bibliography a little cumbersome.

These criticisms are avoided in Supplement I by the inclusion of titles after the authors' names, a distinct improvement.

The same general plan is followed as in the original set, Preface, Instructions to Users, Subject Index Outline, Key to Abbreviations of Names of Journals, Section I Chronological List of References (corresponding to Volume I as published in 1939), and Section II Subject Index Sections, List of Spe-

cies of Anaerobic Bacteria, and Index (corresponding to Volume II as published in 1939).

Section I contains a total of 2,685 entries distributed as follows:

1938.....	1,231 entries
1939.....	1,057 entries
1940.....	397 entries (incomplete)

The external form and binding of the Supplement are identical with those of the original volumes and maintain the usual high standards of the University of California Press.

IVAN C. HALL

About Ourselves—By James G. Needham. Lancaster, Pa.: Cattell Press, 1941. 276 pp. Price, \$3.00.

In 1914 and again in 1939 we were tragically reminded that it is possible for civilized man to revert to his primitive state. The author of this book, a biologist, who also has delved into the development of man's social life, shows us that man is so much animal that for him war appears to be inevitable.

This book is written by a biologist, after many years in the laboratory and field, who has the gift of simplification that appeals to the layman. He treats of man in his biological aspects, showing that in development, structure, and function he is very much like the animal. The "brain is the chiefest of the gifts of the gods to our species" but we find it difficult to control. The driving forces in ourselves are the physiological responses necessary to keep life going. Instincts, such as fear and the preservation of the race, are deep springs of conduct derived from animals. In our social life are folkways that also have come in part from animals and are foundation stones in the social order. Ordinarily reason controls our social order but tribal instincts within and

without nations cause antagonistic groups to fight, impulses and passions become overpowering.

At the close of the book we find that religion in society is a stabilizing influence. "Government drives and organizes; religion leads and sustains."

The book has deservedly received much favorable commendation.

EDWARD C. SCHNEIDER

The Man Who Lived for Tomorrow—By Wade W. Oliver, *New York: Dutton, 1941.* 507 pp. Price, \$3.75.

This book is marked "a biography of William Hallock Park, M.D.," but a careful and eager perusal reveals that it is both more and less. On the positive side may be counted (1) a beautifully written history of diphtheria, and (2) a somewhat less impassionate account of the development of the Bureau of Laboratories of New York City's Health Department. On the negative side there is too little of the man and practically nothing of tomorrow, both of which are disappointing. One might have expected that an eminent scientist with poetical instincts (and there is only one Wade Oliver) would get around to the future in a nice flamboyant style, but one fears that his immersion in a Victorian biography may have clouded his prophetic field of vision. In most spots this volume is a mixture of worshipful and dekuifian (and why not a useful word by now?) science. William H. Park was pretty much of a human being—what a pity that realistic biographies must always be written so long after a man that what appears to be realism is only conjecture.

No review for readers of this *Journal* needs to list the magnificent accomplishments of Park, for he is a part of our times and his life is, and must remain, one of the strongest and most enduring pillars of American public health. Perhaps not to be credited with

the greatest discoveries of his time, he nevertheless possessed the courage to apply the findings of others to everyday public health—and this courage is possessed by few. Along with this courage he had the curious ability to endow all of those in his group with the type of zeal that was almost fanatical in character. One might suppose that few leaders in public health have been worshipped as absolutely as was William H. Park. The reader may search in vain in this biography for any explanation of this peculiar trait.

Oliver has omitted many things and perhaps for good reasons, but he might well have stated the part played by Park in the activities of various professional societies and in the shaping of public health standards, for these facts would have been more worth while than some of the bickerings which are included.

This is indeed a handsome book, beautifully written and beautifully manufactured. KENNETH GOODNER

Cases of Syphilis Under Treatment—Cuyahoga County—March, 1940—By Howard Whipple Green. *Published by Joint Social Hygiene Committee of the Academy of Medicine of Cleveland and The Cleveland Health Council, 1941.* 51 pp.

This is the third annual report in which cases of syphilis under treatment in Cuyahoga County (Cleveland, Ohio) during a given month are analyzed. The data are of significance mainly in relationship to those for the two preceding years.

There were 3.3 cases per 1,000 population under treatment in March, 1940, as compared with 3.8 per 1,000 in March, 1938. The rate for whites was 2.0 per 1,000 and for colored 20.6 per 1,000. Infectious cases comprised 9 per cent of the white cases and 26 per cent of the colored. The number of infectious cases decreased in whites

from 344 in 1938, to 205 in 1940, but increased in colored persons from 330 in 1938, to 441 in 1940. For the month of March, however, the number of new infectious cases among white and colored together was 181 in 1938, 161 in 1939, and 91 in 1940.

These and other data have been analyzed according to race, sex, age, and treating agency. To what extent the figures reflect real changes in the attack rate of syphilis in Cleveland is difficult to say, but it is from this type of painstaking analysis of the available data year after year that reliable evidence regarding the trend of syphilis is likely to come.

THOMAS B. TURNER

Twelve Months of Health Defense
—*Edited by Savel Zimand. Annual Report of the Department of Health, City of New York, 1940.* 283 pp. Price, \$1.00.

This is an account of the activities of the Health Department of New York City for 1940 together with comparative tables on vital statistics and a review of developments since 1934. Inside the front and back covers are effective two page charts which show since 1900, the annual death rates per 1,000 population according to age groups. More detailed subsequent analysis under a heading—The Changing Picture—reveals for this city of some 7½ million persons a death rate in 1940 of 45.7 for the pneumonias, 44.5 for pulmonary tuberculosis, 3.3 for “cholera infantum,” as contrasted with rates in 1901 of 258, 228.9, and 164.1, respectively. There were only 10 deaths from diphtheria in 1940 against 2,068 in 1901 when the population was less than half as large.

The death rate in 1940 from diseases of the heart was over 3 times that of 1901, while that from cancer was over 2¼ times as high as in the earlier year, illustrating factors accompanying the

aging of the population. The decline of infant mortality to 35 per 1,000 live births and the control of acute communicable diseases represent great public health victories. But, as stated in the report, cancer, diabetes, and diseases of the cardiovascular renal group, charged with less than 25 per cent of the mortality in 1901, are now responsible for more than 65 per cent of all deaths in the city. “Some of the increase in these diseases, to be sure, is also due to improved diagnosis. Nevertheless the public health program of the future will undoubtedly have to concern itself more with these three causes of disability and death.”

Under “Seven Years of Progress” reference is made to one of the major achievements—the development of the district health center plan with a unit of department workers and services in the 30 districts of the city, each with a population of about 250,000. Other developments have included a vigorous campaign for the control of syphilis and gonorrhea, mass x-ray surveys to discover tuberculosis, reaching over 303,000 persons (with the death rate reduced by 25 per cent), the conduct of important studies, personnel training through experimental teaching centers and in-training courses, and recent necessary shifts in emphasis to meet emergency conditions.

While the statistical information in the report is extensive, much of the “meat” is presented in a concise and interesting manner in the descriptive text accompanied by 25 effective photographic illustrations of the department in action. Human interest is also added by brief quotations and lively descriptions from the service in the field and health center. Reference to specific subjects is facilitated by a carefully prepared index and a table of contents, the latter carrying among the titles: health defenses, human bookkeeping and health education, centers of public

health, and sanitary protection; and subtitles: the library with the children (referring to the child hygiene services, a pioneer organization developed in 1908), and so to school, the laboratory shows the way, our sanitary corps, and guarding the home front. The last title refers to the 900 public health nurses who every day of the year in clinics, at schools, and in homes, come directly and intimately into contact with the people. This is a stimulating report of progress, carefully planned and ably executed.

IRA V. HISCOCK

The Volunteer in Public Health Nursing — Prepared by Evelyn K. Davis. New York: National Organization for Public Health Nursing, 1941. 48 pp. Price, \$.50.

The Volunteer in Public Health Nursing should be on the desk of every director of a nursing agency and available to her staff members as well as to her board members and volunteers.

This handbook was prepared by Evelyn K. Davis, formerly assistant director of the National Organization for Public Health Nursing and now with the office of Civilian Defense for New England. She has had long experience in work with the lay person and the manual is the result of her many contacts over the country with people who want to help in the health field but lack medical or nursing training.

Miss Davis with great clarity explains why a nursing organization should use the volunteer, and where she can be made useful "so to assist the nurse that her services will go further in the community." She believes that, "a volunteer carefully selected, trained, and supervised may be made to feel a part of the organization."

A very explicit schedule of actual work in clinics, motor corps, etc., has been worked out, and directions for selection, training, and placement of volunteers will serve as a guide in the

use of a layman for any size organization. The handbook is equally important for the staff member and the student nurse as it is only their understanding of the place of the volunteer in their public health program that can make a volunteer feel part of it all.

Today, more than ever before, the appeal from all types of people is "what can I do to help in the Civilian Defense Program?" As health work is recognized as the first line of defense in this World War II, I feel that this handbook provides the answer and offers adequate solution to that question. Miss Davis's book is so full of suggestions that any director who works with volunteers whether it be in a health or a welfare agency could well afford to consult it. PRISCILLA K. THAXTER

Toughen Up, America — By Dr. Victor G. Heiser. New York: McGraw-Hill, 1941. 228 pp. Price, \$2.00.

Dr. Heiser's book of reminiscences, *An American Doctor's Odyssey*, had a well deserved success and gave an interesting picture of the work of a public health physician. *Toughen Up, America* deals with personal hygiene and as the title indicates is hitched to propaganda, with a not very happy result. All writers on personal hygiene are, by the nature of the case, platitudinous but few have achieved such a masterpiece of linked dullness, long drawn out, as Dr. Heiser.

The chapter openings are beacons for all future popular health writers to avoid. "Few of us escape a moment of sharp realization that we must do something about our diet." "Very few of us reach maturity without some period of sleeplessness." "We are a queer lot, we humans." Charity demands that a veil be drawn over other evidence of how banal a civilized man can be when he takes pen in hand and lets his wits drift out of the window.

Dr. Heiser records as a solemn contribution to the science of hygiene that

a doctor in Carlsbad told him, "Your skin is yellow. You have colitis." If that is typical of the medicine they practised in Carlsbad, it is well Carlsbad *delenda est*. *Toughen Up, America* has softened down Dr. Heiser.

LOGAN CLENDENING

Microbes Which Help or Destroy Us—By Paul W. Allen, Ph.D., D. Frank Holtman, Ph.D., and Louise Allen McBee, M.S. St. Louis: Mosby, 1941. 540 pp. Price, \$3.50.

This volume is evidently issued for popular consumption, but one may question its ultimate popularity, for it is too carefully written and too accurately detailed to make vivid reading. The list of subjects covered is truly amazing for a volume of only 540 pages. Practically all infectious diseases, as well as bread making, vinegar, evaporated milk, and manure, are included. One might suggest that there is some lack of balance in the treatment of various subjects and some unevenness in the amount of color found in the text. It is rather a shock to find a popular book which has avoided the journalistic style of presentation.

The volume is set in the usual clear Mosby style but the larger part is printed on a glazed paper with a greenish tint which is supposed to make reading easier but which to this reviewer is very disagreeable. Nevertheless, the volume is commendably accurate.

KENNETH GOODNER

Preeclamptic and Eclamptic Toxemia of Pregnancy—By Lewis Dexter and Soma Weiss. Boston: Little, Brown, 1941. 414 pp. Price, \$5.00.

This attractive volume represents a successful attempt to summarize and bring up to date our present knowledge of the toxemias of late pregnancy. It further includes a large amount of pertinent investigation on the part of the authors themselves. The book differs

from previous works on the subject in that it is written by and presents the point of view of the internist rather than the obstetrician. Particularly to be commended is the chapter on the nature and significance of generalized edema in normal and toxemic pregnancy. There is also a precise and impartial summary of the work which has been done in an effort to correlate endocrine imbalance with the various manifestations of toxemia. Proper emphasis is placed on prophylaxis or adequate prenatal care, on the early treatment of toxemia, and on the importance of termination of pregnancy if improvement does not soon appear. On the debit side one might wish for a more liberal presentation of the various types of modern treatment, and particularly of eclampsia. Also more space might well have been allotted to the remote effects of the toxemias as related to chronic vascular disease and in this regard many authorities will probably deprecate the section on pregnant hypertension uninfluenced by pregnancy, a phenomenon which, in the experience of the reviewer, is very rarely seen. The book is to be recommended for the investigator and specialist but is doubtless not intended for the average student or practitioner.

CHARLES H. PECKHAM

We Need Vitamins—By Walter H. Eddy and G. G. Hawley. New York: Reinhold, 1941. 102 pp. Price, \$1.50.

This book is without doubt one of the best written, concise and informative books for the laymen and non-nutritionists that have yet been published. It can be read in a few hours or in a couple of evenings. The information is accurate, up-to-date, and yet written in non-technical language which the average lay person can fully understand. Much of the text is in narrative form, that is, questions and answers, and this aids much in reliev-

ing the usual monotony of perusing scientific or technical books.

The appendix contains a very useful table of vitamin content of foodstuffs. Instead of confounding the reader by referring to half a dozen different vitamin units, the authors are very careful to give unit equivalents in every case. They also give values for the average serving. This information is of particular value to dieticians. The reviewer highly recommends this little book. It is literally packed with vitamins.

C. R. FELLERS

Immunization to Typhoid Fever—
By Colonel J. F. Siler and others. *The American Journal of Hygiene Monographic Series, No. 17.* Baltimore: Johns Hopkins Press, 1941. 276 pp. Price, \$2.50.

This comprehensive report of seven years' experimental investigation by scientists of the United States Army Medical School research laboratories is an outstanding contribution to our knowledge of immunization against typhoid fever.

After a historical review of results in the preventive programs of the Army, Navy, and Civilian Conservation Corps, the authors present their experimental

studies on the influence of antigenic structure of *Eberthella typhosus* used for vaccine preparation in the production of immunity as measured by mouse protection tests. This is followed by observations on the duration of immunity and on methods of revaccination. Each phase of the investigation is discussed in detail and results are presented in a logical and orderly manner well documented with tables, sample protocols, and a series of appendices explaining details not given in the main text. The authors, in summarizing their findings, lay down criteria for selection of strains to be used for vaccine preparation and for keeping such strains in suitable condition. They recommend a continuance of the standard three dose method for initial immunization but prefer a single dose intracutaneous method for reimmunization.

There is need for more such critical studies of methods in public health practice and it is pleasant to record that the authors indicate that these investigations are to be continued by similar studies on immunization against paratyphoid fevers and consideration of problems of cross-immunization.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Be Prepared—Read this editorial (and some of the references) about *C. diphtheriae* gravis, the deadly form that kills despite immune serum. Except recently, in Halifax, this type hasn't made headway on this continent. But under war time conditions who can foretell when it will?

ANON. Newer Knowledge of Diphtheria Gravis. J.A.M.A. 118, 5:380 (Jan. 31), 1942.

Our Gory-ous Fourth—More evidence is offered through this annual compilation that legislation plus effective enforcement will reduce deaths and injuries from fireworks. The nationwide total declined handsomely in 1941, but if states which haven't them, would enact effective laws, and some other states would enforce the ones they have, the good record might be further improved.

ANON. Fifth Annual Summary of Fourth of July Injuries. J.A.M.A. 118, 1:46 (Jan. 3), 1942.

Department of Human Genetics—As generation of Yale students follows generation they enter younger and are heavier and taller. Half a century ago one student in 20 was over 6 feet tall. Today the 6 footers are 1 in every 5. Physicians, sanitarians, nutritionists, educators all may lay some claim to sharing in this phenomenon.

DEEGAN, W. A Forty-nine Year Survey at Yale Reveals Freshmen Are Becoming Younger, Heavier, and Taller. Research Quart. 12, 4:707 (Dec.), 1941.

More Than Medicine is Needed—Intimate exposure and poverty are the two conditions that most favor tuberculosis. Where they meet, double pro-

tection is needed and this implies more than free medical care and treatment. These wise words from one of our late and great public health statesmen are given new meaning by this Harlem study.

DOWNES, J., and PRICE, C. R. The Importance of Family Problems in the Control of Tuberculosis. Milbank Quart. 20, 1:7 (Jan.), 1942.

Tuberculosis-Saboteur — In the Navy the incidence of tuberculosis is not high, and the thorough methods employed to exclude tuberculous recruits will result in a continued decline of the disease. Fluorography with the 35mm. film is used, with a standard film retake for checking questionable cases. Tuberculosis in veterans, having cost the country a cool billion since the World War, is also a matter of concern to the Army. Draftees, generally, will have chest fluorographic examination using the 4" x 5" film.

DUNCAN, R. E. Pulmonary Tuberculosis (and) POLLOCK, W. C. Tuberculosis in the Army. Am. Rev. Tuberc. 44, 6:651 (Dec.), 1941.

Diet Does It—Diets of 400 women during their prenatal period were recorded. Some on poor diets were allowed to go on as controls. Others, previously poorly nourished, had their poor diets supplemented. Still others, already on good diets, were helped by education. Those on good or supplemented diets had fewer complications, were better obstetrical risks, had fewer miscarriages, stillbirths, and premature births than those on poor diets, and among the resulting infants there were fewer illnesses and deaths. This excel-

lent paper will well repay study. Don't be satisfied with this inadequate note upon it.

EBBS, J. H., *et al.* The Influence of Prenatal Diet on the Mother and Child. *Milbank Quart.* 20, 1:35 (Jan.), 1942.

Which Tuberculin Test?—For case finding surveys, the patch test may prove more efficient than the intracutaneous test, if the well known loss from needle shyness is taken into account; so concludes this painstaking study.

FURCOLOW, M. L. Quantitative Studies of the Tuberculin Reaction. *Pub. Health Rep.* 56, 51:2405 (Dec. 19), 1941.

Prepared for Polio—For a good, workman-like report of a well conceived control project to deal with an anticipated outbreak of poliomyelitis, I suggest you write for the issue of the Maryland bulletin named below. With federal aid, the health officers aimed to secure immediate and complete reporting, early hospital, or supervised home care, and competent after-care, and these aims must have been very largely achieved.

HALLIDAY, C. H. Poliomyelitis Situation in Maryland. *Maryland State Dept. of Health Monthly Bull.* 13, 9:77 (Nov.), 1941.

Germ on Lip of the Cup—Ignorance of sanitary procedures by managers and employees appears to be the chief cause of insanitary practices. It seems that the health engineering profession (in the city studied, at least) is not utilizing education as a tool to improve public eating and drinking places. This is the inescapable conclusion of a (Providence, R. I.) bacteriologic sampling of silver and glassware.

HORWOOD, M. P., and PESARE, P. J. The Sanitation and Bacteriology of Public Eating Utensils. *Pub. Health Rep.* 57, 2:33 (Jan. 9), 1942.

Encouragement for Oldsters—You will remember Osler's often misquoted crack about the unproductiveness of old-timers, even if you did not read an earlier study by the author of this paper which indicated that most creative thinking was done when the thinker was in his thirties. Now comes a study which indicates that the top of the political ladder (in any field, scientific as well as social) is most often reached by men in the late fifties.

LEHMAN, H. C. Optimum Ages for Eminent Leadership. *Sci. Month.* 54, 2:162 (Feb.), 1942.

Page Mrs. Sanger—Australia's long continued decline in fertility rates (the net reproduction rate has now sunk below the rate required for replacement) is evidence that declining fertility is a characteristic of new as well as old countries. It cannot be attributed to "militarism," or to democracy. Research is needed in causes and consequences.

MCCLEARY, G. F. Australia's Population Problem. *Milbank Quart.* 20, 1:23 (Jan.), 1942.

Note for School Medical People—Lethane in deodorized kerosene sprayed with a flit gun proves to be the most successful method of removing head lice in this Canadian experience. It is reported that no other treatment has been received with such gratification and enthusiasm by the parents.

MACHAFFIE, L. P. Pediculosis—A New Treatment. *Canad. Pub. Health J.* 32, 12:606 (Dec.), 1941.

Diphtheria Carriers—Children with tonsils intact are more often carriers of diphtheria than are those who have had this lymphoid tissue removed. There is much more in this continuing exploration in an old field.

MAXCY, K. F., *et al.* Diphtheria in Baltimore: Tonsillectomies as Related to the Diph-

theria Carrier Rates. *Am. J. Hyg.* 35, 1:42 (Jan.), 1942.

Polio Flies—Here is more proof that house flies may carry poliomyelitis virus—this time from Cleveland and Atlanta.

SABIN, A. B., and WARD, R. Flies as Carriers of Poliomyelitis Virus in Urban Epidemics. *Science* 94, 2451:590 (Dec. 19), 1941.

Radiant Disinfection of Air—You will want to know about this study to test the hypothesis that epidemic contagion is spread in confined atmospheres and can be controlled by radiant disinfection. It seems too bad to spoil the story by telling the results, which did support the hypothesis. Measles epidemics were much reduced as com-

pared with control rooms. Colds weren't helped—presumably because they are more often contracted in intimate outside contacts.

WELLS, W. F. The Environmental Control of Epidemic Contagion. *Am. J. Hyg.* 35, 1:97 (Jan.), 1942.

Air, Vapor, and Oral Mucosa—Health educators sometimes talk pretty glibly about our over-heated homes, the kiln-dried air therein, the arid nasal mucosa, and the resulting colds we enjoy. A survey of the factual data presented in this excellent paper will tend to make such hygienic pronouncements a little less pontifical.

WINSLOW, C.-E. A., *et al.* The Influence of Atmospheric Temperature and Humidity upon the Dryness of the Oral Mucosa. *Am. J. Hyg.* 35, 1:27 (Jan.), 1942.

ASSOCIATION NEWS

SEVENTY-FIRST ANNUAL MEETING

ST. LOUIS, Mo., OCTOBER 27-30, 1942

Headquarters

MUNICIPAL AUDITORIUM

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Oswald De N. Cammann, M.D., New Canaan, Conn., Health Officer
Edmond Klamke, M.D., M.P.H., Webster Health Unit, Minden, La., Director
Walter S. Kotas, M.D., 1512 E. 22nd St., Cheyenne, Wyo., Laramie County Health Officer
John R. Long, M.D., Perry County Health Dept., Marion, Ala., Health Officer
Samuel N. Mallison, M.D., Butler County Health Dept., ElDorado, Kan., Director
Raymond F. Mayer, M.D., Claiborne County Health Dept., Port Gibson, Miss., Director
Pedro Orpi, Jr., M.D., Stop 20, Ave. Hipodromo Esq. Duarte, Arecibo, Puerto Rico, Medical Officer, Health Dept.
Frank L. Quillman, M.D., P. O. Box 446, Apalachicola, Fla., County Health Officer, Gulf-Franklin-Wakulla Health Unit
Paul D. Robason, M.D., 207½ E. Virginia, McKinney, Tex., Collin County Health Officer

Laboratory Section

Norma B. Carroll, B.S., 214 West Jones, Raleigh, N. C., Senior Bacteriologist, State Laboratory of Hygiene
Dr. Teodoro Drake, M. Ortiz 441, Redencion, Marianao, Havana, Cuba, Assoc. Bacteriologist, Children's Hospital
Francisco J. Dy, M.D., 615 N. Wolfe St., Baltimore, Md., Asst. Instructor of Parasitology, Institute of Hygiene, Univ. of the Philippines
Roslyn U. Fishman, B.A., 917 Ave. N., Brooklyn, N. Y., Laboratory Asst., New York City Dept. of Health
Mildred M. Galton, M.S., 6936 Bloxham Ave., Jacksonville, Fla., Senior Bacteriologist, State Board of Health

Daniel Kaminsky, M.S., State Hygienic Laboratory, Jackson, Miss., Bacteriologist, U. S. Public Health Service
Camille Lherisson, M.D., 46 John Brown Ave., Port au Prince, Haiti, Professor of Parasitology, National School of Medicine
Roy S. Madden, Jr., U. S. S. Relief c/o Postmaster, New York, N. Y., Laboratory Technician. U. S. Navy
Stanley Margoshes, M.S., 319 Medical Dormitory, Chapel Hill, N. C., Student and Assistant, Univ. of North Carolina School of Public Health
Mollie Mollov, M.S., 150-75-87th Ave., Jamaica, N. Y., Bacteriologist, Queens General Hospital
Charles G. Ransom, B.S., 706 Church St., Doctors Bldg., Nashville, Tenn., Consultant Bacteriologist, Davidson County Health Dept.

Vital Statistics Section

Ruth E. Cramer, Municipal Bldg., East Liverpool, Ohio, Registrar of Vital Statistics, City of East Liverpool
Andrew S. Wong, M.P.H., 1226 9th Ave., Honolulu, T. H., Director, Bureau of Vital Statistics, Board of Health

Engineering Section

Robert J. Boes, M.S., 515 Huff St., Winona, Minn., Public Health Engineer
Henry E. Breedlove, M.S., Board of Health, Mobile, Ala., Public Health Engineer
Charles E. Carl, M.S., Jackson County Health Dept., Independence, Mo., Public Health Engineer
Vernon B. Hammer, M.S., Des Moines County Health Unit, Burlington, Iowa, Junior Public Health Engineer, U. S. Public Health Service

Charles Haydock, B.S., Commercial Trust Bldg., Philadelphia, Pa., Consulting Engineer

Carman G. Leonard, M.S.P.H., 891 North Church St., Spartanburg, S. C., Senior Sanitary Officer, State Board of Health

Howland C. Lutz, B.S., Glen Rock, Pa., Assistant Public Health Engineer, U. S. Public Health Service

Edward N. McKinstry, B.S., 2813 Farragut St., Bremerton, Wash., Assoc. Public Health Engineer, U. S. Public Health Service

Richard F. Poston, M.S., Box 2929, Juneau, Alaska, Acting Director, Public Health Engineering, Territorial Health Dept.

Jack W. Pratt, 2589 LeConte Ave., Berkeley, Calif., Asst. Sanitary Engineer, State Dept. of Public Health

P. Edward Riley, B.S., 1800 W. Fillmore St., Chicago, Ill., Asst. Milk Sanitarian, State Dept. of Public Health

J. L. Rowland, Jr., A.B., Oak Park Health Dept., Oak Park, Ill., Chief Milk Sanitarian

James A. Sampson, B.S., Court House, Fort Dodge, Iowa, Public Health Engineer, State Dept. of Health

Maurice A. Shapiro, A.B., Area Health Office, Hinesville, Ga., Junior Public Health Engineer, U. S. Public Health Service

Industrial Hygiene Section

Forrest H. Bumford, B.S., 12 Park St., Concord, N. H., Asst. Sanitary Engineer, U. S. Public Health Service

Harry Heimann, M.D., 5402-6th Ave., Brooklyn, N. Y., Senior Industrial Hygiene Physician, New York State Dept. of Labor

Joseph Shilen, M.D., 432 South Office Bldg., Harrisburg, Pa., Director, Bureau of Industrial Hygiene, State Dept. of Health

Food and Nutrition Section

Robert O. Baird, M.S., Box 900, Bismarck, N. D., State Food Commissioner and Chemist, State Laboratories Dept.

G. LeMar Johnson, B.S., Box 103, Eaton, Ohio, Sanitarian, Preble County Board of Health

Maternal and Child Health Section

Annette V. Kitzmiller, Nome, Alaska, Public Health Nurse, Territory of Alaska

Robert M. Robbins, M.B., 155th and State Sts., Flushing, L. I., N. Y., Supervising School Health Physician, New York City Dept. of Health

Public Health Education Section

Amalia C. Baird, 211 Garfield Ave., Eau Claire, Wis., Member, State Board of Health

A. Laurence Corbman, D.D.S., 5350 Gainor Rd., Philadelphia, Pa., Staff Dentist, Children's Hospital of Philadelphia

Dr. Eli Eichelberger, 308 S. George St., York, Pa., Director of Public Health

Lyla D. Flagler, 1614 State St., Eau Claire, Wis., Teacher, Science and Home Economics, State Teachers College

Adolph E. Franke, 222 Pine St., Williamsport, Pa., Sanitarian, State Dept. of Health

Etta Mueller, Memorial Hospital, Lima, Ohio, Superintendent of Nurses

Maurine G. Muller, A.B., 1554-28th Ave., San Francisco, Calif., Clerk, Welfare Division, Metropolitan Life Ins. Co.

Public Health Nursing Section

Ruth Addams, R.N., B.S., 1307 Spruce St., Philadelphia, Pa., Public Health Nurse and Instructor, The Presbyterian Hospital

Grace Anderson, R.N., R.F.D. 1, Titusville, N. J., Territorial Supervisor of Nursing, Metropolitan Life Ins. Co

Mildred J. Davis, 35 State St., Batavia, N. Y., Supervising Public Health Nurse, State Dept. of Health

Ruth Freeman, R.N., M.A., 95 N. Lexington Ave., St. Paul, Minn., Director of Course in Public Health Nursing, Univ. of Minnesota

Wilma E. Gross, R.N., Mt. Sterling, Ill., District Unit Nurse, Dept. of Public Health

Rose Guralnick, M.A., R.N., P. O. Box 356, Seward, Alaska, Public Health Nurse, Seward Public Health Service

Hilkea Jacobs, B.S., C.P.H., Cobblestone Apts., Kemmerer, Wyo., Supervisory Nurse, State Dept. of Health

Hazel F. Kandler, R.N., B.S., Rt. 1, Box 640, Tucson, Ariz., Supervising Nurse, Dept. of Health

Marcelle Kelly, M.A., 2101 Adelbert Rd., Cleveland, Ohio, Staff Nurse, Maternal Health Assn.

Bivion L. Kimbrell, R.N., A.B., 1053 Madison Ave., Memphis, Tenn., Local Supervisor, Metropolitan Life Ins. Co. Nursing Service

Enid Mathison, B.S., DeFuniak Springs, Fla., County Nurse, State Board of Health

Margaret M. McCulloch, 415 S. Fifth Ave., Apt. 2, Ann Arbor, Mich., Public Health Nurse Trainee (New Mexico State Public Health Dept.)

Fannie A. Munroe, Quincy, Fla., Staff Nurse, Gadsden County Health Dept.

Esther Putnam, R.N., Bannock County Health Unit, Pocatello, Ida., School Nurse

Rose Wendrow, Health Dept., Chicopee, Mass., Public Health Nurse, Chicopee Health Dept.

Margaret C. Wolcott, M.A., 530 West Water St., Elmira, N. Y., Supervising Public Health Nurse, State Dept. of Health
 Margaret Young, B.A., Irwinville, Ga., Project Nurse, Irwinville Farms, Farm Security Administration

Epidemiology Section

Lynne E. Baker, M.D., Florida State Board of Health, Jacksonville, Fla., Director, Division of Tuberculosis
 I. Jay Brightman, M.D., Fuller Gardens, Ossining, N. Y., Consultant, Division of Syphilis Control, State Dept. of Health
 Abe A. Goldman, M.D., Cumberland Hospital, 39 Auburn Place, Brooklyn, N. Y., Interne, New York City Dept. of Hospitals
 David Reisner, M.D., 17 E. 96th St., New York, N. Y., Medical Supervisor, Bureau of Tuberculosis, Dept. of Health

Unaffiliated

William Bolt, M.D., C.M., 51 Madison Ave., New York, N. Y., Medical Director, New York Life Ins. Co.
 Stephen Cahana, M.D., 152 W. Wisconsin Ave., Milwaukee, Wis., Vice President, Wisconsin State Board of Health
 Arthur S. Lynn, Aulston Ave. Ext., Durham, N. C., Trainee in Public Health, Univ. of North Carolina, School of Public Health
 Irwin Rothman, V.M.D., 2233 N. 18th St., Philadelphia, Pa., Veterinarian, U. S. Dept. of Agriculture

DECEASED MEMBERS

Justus Goslaw, M.D., Cedar Grove, N. J., Elected Member 1938, Laboratory Section
 Clifford B. Line, D.V.M., Lansing, Mich., Elected Member 1940, Laboratory Section

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearing house on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

U. S. CIVIL SERVICE COMMISSION

The U. S. Civil Service Commission, Washington, D. C., announces unassembled examinations for Home Economists in 5 different grades at \$2,600 to \$5,600 a year. Interested persons should apply to the Commission for Circular 195 on Home Economics.

Junior Public Health Nurse. A civil service examination for Public Health Nurse (\$2,000) has been open for some time. Nurses who have been unable to qualify for this examination because of the experience requirement now have an opportunity to qualify through a new Junior Public Health Nurse examination (\$1,800) which requires no experience. Applications are also being received for examinations now open for Junior Graduate Nurse (\$1,620) and Graduate Nurse for general staff duty (\$1,800). Further information and application forms may be obtained at any first or second class post office or from the Civil Service Commission, Washington.

POSITIONS AVAILABLE

County Public Health Nurses for New Mexico. Must have four months' post-graduate instruction under one of the recognized public health nursing courses and one year's experience. Must drive and have a car. Address inquiry to State Health Department, Santa Fe, N. M.

Physician with either public health training or experience in local health department administration to serve as health director in a county health department in mid-western state. Salary \$4,000 and \$500 travel (flat rate). Well established department with offices in attractive little city of 10,000. Write Box T, Employment Service, A.P.H.A.

Wanted: Trained Public Health Nurse, starting salary \$1,500 per year and traveling expense, increase to \$1,700 within 6 months. Saginaw County Health Department, Saginaw, Mich.

The State Department of Social Security and Welfare, Crippled Children's Division, of Phoenix, Ariz., has three vacancies to be filled. Examinations will soon be held for orthopedic nursing consultant, nurse-physical therapist, and medical social worker.

Further information may be obtained by writing to the Merit System Supervisor, Room 208, 128 North First Avenue, Phoenix, Arizona.

PHYSICIANS WANTED IN CINCINNATI

Carl A. Wilzbach, M.D., Commissioner of Health of Cincinnati, has announced that there are vacancies for white male

physicians, aged 23 to 50, graduates of recognized colleges of medicine, licensed to practise in Ohio, for appointment to the Cincinnati Health Department. Duties include surveillance over communicable disease, infant and child welfare work, medical service for sick poor, epidemiological surveys of communicable disease, examinations for work certificates, school teachers, etc., vaccination, medical school inspection. Salary \$2,640 to \$3,360 plus transportation allowance of \$240 per annum. Eligible for a retirement system. Persons interested should communicate with Dr. Wilzbach, Commissioner of Health, City Hall, Cincinnati, Ohio.

PUBLIC HEALTH ENGINEER

Responsible professional public health engineering involving field investigations and office studies in the application of sanitary measures. The more difficult engineering and sanitation field surveys include supervision over public water supplies, sewerage systems and sewage treatment plants and review of plans for same, and promotion and supervision of sanitation programs. Minimum qualifications: Training and experience equivalent to 3 years' civil engineering experience, including 2 years in public health or sanitary engineering; or completion of an academic year of graduate study and a year's experience in sanitary or public health engineering; and graduation from a college of recognized standing with a major course in civil or sanitary engineering. The salary range is \$205 to \$250 per

month depending upon experience. Apply Box E, Employment Service, A.P.H.A.

Southwestern State Health Department seeks 2 physicians for assignment to district health units, personally to conduct several small venereal disease clinics on a rotating schedule. Experience preferred but not required. Salary \$3,000, plus actual travel allowance not to exceed \$1,200. Write Box V, Employment Service, A.P.H.A.

Middle western city, 125,000 population, seeks well trained and experienced Health Officer on full-time, with competence to administer a department and teach public health to medical students. Salary \$5,000 to \$5,500 per annum. Write Box K, Employment Service, A.P.H.A.

Bacteriologist, M.S. or Ph.D., with 3-5 years' applied experience in the field of sanitation and disinfection, wanted by prominent eastern manufacturer for re-

search and development work. Creative ability must be established. Consideration will be given only to those who fully meet the above requirements. In replying give full academic, industrial and personal background. Transcript of academic record, scientific and personal references, and recent photograph will be requested. Write Box P, Employment Service, A.P.H.A.

The New Mexico State Department of Health will consider applications for the position of Assistant Director of the Maternal and Child Health Division and for Dental Health Consultant of that Division. Address inquiries to the State Department of Public Health, Santa Fe, N. M.

Instructor in Bacteriology. Medical School, large midwestern university. M.D. (or Ph.D. or D.Sc. in Bacteriology); Male. Salary \$1,800 to \$2,500 according to age and experience. Write Box D, Employment Service, A.P.H.A.

POSITIONS WANTED

ADMINISTRATIVE

Teaching or administrative position desired by physician, aged 48. Experienced teacher in preventive medicine and public health, now employed at prominent medical school. Twenty years' experience in municipal health administration and epidemiology. A-491.

Physician, M.D. Tulane, M.P.H. Johns Hopkins, age 31, experienced as health unit director, prefers administrative position in the South. A-488

Physician, age 32, 5 years clinical and administrative experience in venereal diseases, wishes administrative position in venereal disease control, preferably at state level. A-490

HEALTH EDUCATION

Teacher and research worker, man, Ph.D., age 52. Extensive record as college professor of biology and hygiene and investigator, for the past two years engaged in research. H-499

Health Educator, Negro, man with background of High School administration and M.S.P.H. from Michigan, seeks position in Health Education. Public agency or educational field. Excellent references. H-497

Woman, M.S. in public health, excellent graduate training in education, 8 years' experience as business executive (sales and publicity). Just completed year's research in community education. Seeks good administrative position. H-496

Health Educator, M.A. in Education, 10 years' background in community organization for public health education, also teaching of personal and community health at high school and college levels. Public health nurse, able to teach mental and social hygiene as well as general health education. East preferred. H-498

Health Educator. Man with M.S. in preventive medicine and public health. Negro. Seeks position in Health Education or field work with official or non-official agency. H-500

Woman with master's degree in health education, 12 years' successful experience in public school and college teaching, administration and research. Will consider position in normal school, public schools, or in official or nonofficial health agencies. Prefers South or East. Available at once. H-501

LABORATORY

Milk Sanitarian and Technologist, age 37, Ph.D. Bacteriology, Wisconsin, 10 years' experience in milk and food sanitation from industrial and official angle, seeks administrative position with opportunity for research or investigational work preferred. L-381

Chemist, Sc.D., Biochemistry, Johns Hopkins University. Age 31. Public health laboratory experience, teaching experience. Desires position with promise of advancement, preferably in commercial organization. L-461

Bacteriologist, young man, 28, with B.S. in industrial science, experienced in newspaper work, salesmanship and now employed in a state department of health laboratory, seeks position as bacteriologist or doing promotional work of public health nature. L-465

SANITARY ENGINEERING

Public Health Engineer, M.S. Harvard, experienced in public health and industrial hygiene, wishes position of better sort in public health engineering or industrial hygiene. E-470

STATISTICAL

Woman with academic, business and research experience in vital statistics, seeks a position in the vital statistics division of a state or city health department, preferably as registrar. S-459

Experienced and well trained public health nurse, with background of tuberculosis, venereal disease, school, industrial, and generalized services, will shortly be available for appointment. Three years as director of state nursing service. Experienced as university teacher of public health nursing. M.A., New York University. M-449

Opportunities Available

PUBLIC HEALTH PHYSICIANS—(a) City health officer; college and industrial town of 25,000; woman physician eligible; around \$4,000. (b) County health officer; opportunity for extensive private practice in rural area; estimated monthly income, around \$500; Washington State. (c) Field epidemiologist, division of venereal disease control; eastern state. (d) County health director; special public health training not required; \$4,600, including automobile allowance; Oklahoma. (e) Assistant director, division of maternal and child health; postgraduate training obstetrics required; woman physician eligible; West. (f) City-county physician; full-time appointment in fairly large town; Georgia. PH3-1, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

PUBLIC HEALTH NURSES—(a) Public health nurse with background of experience in tuberculosis nursing to carry on tuberculosis control work; county appointment; \$150, transportation in county car furnished; Pacific Coast. (b) For appointment in clinic of 300 bed hospital; duties will include

supervision of student nurses giving visiting nurses' service in homes; South. (c) County health appointment; duties include general public health nursing, some obstetrical delivery service, small amount of social service work; Midwest. (d) Assistant supervisor of school nurses; supervision will extend to both educational and field work; \$1,800, transportation allowance; headquarters will be in central city of 300,000. PH3-2, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

BACTERIOLOGISTS—(a) Bacteriologist-serologist; excellent Chicago hospital; degree, personal interview required; \$150, partial maintenance, increasing. (b) Junior bacteriologist for large hospital serving training camp; enthusiasm more important than extensive experience; around \$1,500, traveling expenses to field. (c) Assistant bacteriologist-serologist, city laboratory; duties include assisting in serology, milk, water and restaurant bacteriology, general bacteriology; \$1,500, to begin; ample opportunity for advancement; New York State. PH3-3, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

Situations Wanted

INDUSTRIAL HYGIENIST—B.S., M.D., eastern schools; M.P.H., Harvard School of Public Health; municipal health physician, two years; several years, assistant director, state industrial hygiene bureau. PH3-4, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

PUBLIC HEALTH PHYSICIAN—A.B., state university; M.D., Harvard; M.P.H., Johns Hopkins School of Hygiene and Public Health; graduate training in pediatrics before specializing in public health medicine; six years, assistant commissioner, metropolitan health department. PH3-5, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

PUBLIC HEALTH NURSE—B.S. and M.S. degrees in administration in public health nursing, eastern university; active in public health administration for many years; keenly interested social problems; now educational director visiting nurse association. PH3-6, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

BACTERIOLOGIST—Desires position, preferably in public health laboratories; B.A., eastern school; C.P.H. and Ph.D. (bacteriology), Yale University; has done considerable research; four years, bacteriologist and research technician, public health laboratories. PH3-7, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

NEWS FROM THE FIELD

PUBLIC HEALTH NURSING IN HONOLULU EMERGENCY

SUPPLEMENTING the account carried in February *Journal* of the activities in the Territorial Board of Health during the recent emergency in Hawaii, Mary Williams, R.N., the Director of the Bureau of Public Health Nursing of the Territorial Board of Health, writes that the Board had long planned for essential health measures in an emergency and was in active service immediately. Prompt and efficient communicable disease control measures were instituted and every assistance in medical, sanitary, and nursing aid was given to the military and civil authorities.

"A number of Board of Health nurses got into active service the first few hours and days in hospitals and first-aid stations, but were released to their regular jobs as soon as possible. Perhaps one of our most important services was out in the field reassuring families and particularly maternity patients. Every one of these was visited, plans for delivery were checked, and provision made for hospital or home care. Nurses were on 24 hour call for any emergency home cases. We had the necessary official passes, automobiles, gasoline, and equipment to go anywhere. We were able to give assistance to the evacuees as families were moved immediately from danger zones and housed in public buildings. Subsequent evacuation orders in certain areas have continued this work."

WESTERN BRANCH, A.P.H.A., TO MEET IN SEATTLE

W FORD HIGBY, Secretary of the Western Branch of the American Public Health Association, has announced that the Branch will meet

in Seattle, May 26 to 29 inclusive, with headquarters at the Hotel Olympic. The first day, Tuesday, May 26, will be reserved for meetings of affiliated groups.

Dr. Adolph Weinzirl of the University of Oregon Medical School, Portland, is Chairman of the Program Committee.

COURSE OF LECTURE CONFERENCES ON HEALTH EDUCATION IN NEW YORK

THE Welfare Council of New York City through its Health Education Section has announced a course of lecture conferences on the scientific foundation of health education. The course is arranged for health educators of New York City by the Subcommittee on Scientific Sessions of the Health Education Section. Dr. Iago Galdston is Chairman, Hazel Corbin and Lucy Gillett are members of the committee.

The January lecture was by Dr. J. B. Youmans of Vanderbilt University Medical School, Nashville, Tenn., on Nutrition and Health Education. The February lecture was by Dr. John Romano of the Harvard Medical School, Boston, on Mental Hygiene.

The three forthcoming sessions are listed below. The conferences are to be held at the New York Academy of Medicine, 2 East 103rd Street, New York, N. Y., 3:30 to 5 P.M. on the dates indicated. Cards for admission to the series may be secured by addressing Dr. Galdston at the Welfare Council, 44 East 23rd Street, New York, N. Y.

March 25—Dr. Bernhard J. Stern, Department of Sociology, Columbia University, New York, N. Y.—Sociology.

April 30—Philip Lennen, President, Lennen & Mitchell, New York, N. Y.—Instruments of Education and Propaganda.

May 28—Dr. Perrin Long, Johns Hopkins University, Baltimore, Md.—Hygiene—Public Health.

VITAMIN D VALUE OF SUNLIGHT IN VARIOUS CITIES

THE Wisconsin Alumni Research Foundation of Madison, Wis., announces the publication of a new chart entitled "Facts Regarding the Vitamin D Value of Sunlight in Your City." Concise information is available on clear days and hours of sunshine for each month for 67 cities in the United States. Single copies will be sent free upon request.

NATION-WIDE IMMUNIZATION CAMPAIGN

ELSEWHERE in this issue the Child Health Day proclamation by President Roosevelt focuses the attention of the public on the desirability of having all children in the United States immunized against smallpox and diphtheria. Sponsoring this campaign are the Conference of State and Provincial Health Authorities of North America and the Children's Bureau of the U. S. Department of Labor. The Office of Education, the Public Health Service and state and local health departments and the public schools throughout the nation are expected to coöperate. Main emphasis is placed upon diphtheria and smallpox but it is pointed out that physicians in some areas will also advise immunization of children against whooping cough, tetanus, or typhoid.

Pointing out that there were almost 17,000 cases of diphtheria in 1941, Dr. Martha M. Eliot, Associate Chief of the Children's Bureau, emphasized the fact that neglect of these life-saving preventive measures now takes a heavy toll in illness and death of children. Dr. Eliot expressed the opinion that only by continuing to apply our knowledge of vaccination can we prevent smallpox from returning in the form of virulent epidemics. She noted that in 1941 there were 1,368 reported cases of smallpox in the United States. Dr. Eliot referred to the widespread shifts of

population that result from the mobilization of fighting men and of the labor army and which are apt to increase the hazards of disease. It is therefore more urgent than ever, she said, in this wartime period, and in view of the prospective shortage of doctors and nurses in many communities, to protect the army and industries from the dangers of these diseases so common among children.

The aim of the program is to extend the immunization to 100 per cent of children beyond 9 months of age by May 1, Child Health Day, 1942.

MEDICAL VISITORS FROM CHILE

NINETEEN Chilean physicians are in the United States visiting medical and public health facilities under the guidance of Dr. Hugh S. Cumming, the Director of the Pan American Sanitary Bureau, Washington.

Nine of these physicians have spent considerable time in Michigan as guests of the W. K. Kellogg Foundation, the Detroit Department of Health, and the University of Michigan. They have also visited the Board of Health of Chicago and have recently been to Cincinnati and Nashville. Their special interests are pediatrics, tuberculosis, and maternal health. They are health officers in their districts under the national insurance plan in Chile.

These men include:

Dr. Honorio Aguirre
Dr. Victor Sierra
Dr. Oscar Illanes
Dr. Jorge Abasolo
Dr. Manuel Marin
Dr. Pedro Martini
Dr. Raul Cantuarias
Dr. Luis A. Diaz
Dr. Gabriella Duco

HEALTH CONGRESS IN MEXICO

SCIENCE announces that the first Mexican Congress of Internal Medicine will be held in Mexico City from May 3 to 10, under the aus-

pices of the President of Mexico and the Departments of Education and Public Health, with the coöperation of the medical societies of Mexico and the National University.

DR. BAEHR APPOINTED TO HEALTH AND
MEDICAL COMMITTEE

PRESIDENT Roosevelt has appointed Dr. George Baehr, Chief Medical Officer of the Office of Civilian Defense, to be a member of the Health and Medical Committee of the Office of Defense Health and Welfare Services. Dr. Irvin Abell, Louisville, Ky., chairman of the Committee on Medical Preparedness of the American Medical Association, is chairman of the Health

and Medical Committee, and other members are the Surgeon General of the U. S. Army, Major General James C. Magee; the Surgeon General of the U. S. Navy, Rear Admiral Ross T. McIntire; the Surgeon General of the U. S. Public Health Service, Dr. Thomas Parran, and the chairman of the Division of Medical Sciences, National Research Council, Dr. Lewis W. Weed, Baltimore. The Office of Defense Health and Welfare Services is a part of the Office for Emergency Management which in turn is part of the Executive Office of the President. The director of the ODHWS is Paul V. McNutt, who is also Federal Security Administrator.

CHILD HEALTH DAY—1942

BY THE PRESIDENT OF THE UNITED STATES OF AMERICA
A PROCLAMATION

WHEREAS, the Congress by joint resolution of May 18, 1928 (45 Stat. 617), has authorized and requested the President of the United States to issue annually a proclamation setting apart May 1 as Child Health Day:

NOW, THEREFORE, I, FRANKLIN D. ROOSEVELT, President of the United States of America, in recognition of the vital importance of the health of children to the strength of the Nation, do hereby designate the first day of May of this year as Child Health Day.

And I call upon the people in each of our communities to contribute to the conservation of child health and the reduction of illness among children by exerting every effort to the end that before May Day, Child Health Day, children over nine months of age be immunized against diphtheria and smallpox, the two diseases for which we have the surest means of prevention.

IN WITNESS WHEREOF, I have hereunto set my hand and caused the seal of the United States of America to be affixed.

DONE at the City of Washington this sixth day of February in the year of our Lord nineteen hundred and forty-two and of the Independence of the United States of America the one hundred and sixty-sixth.

FRANKLIN D. ROOSEVELT

(SEAL)

By the President:
CORDELL HULL
Secretary of State.

DENTAL HEALTH

THE National Dental Hygiene Association on February 1 brought out its first edition of a new quarterly magazine entitled *Dental Health*, devoted to the promotion of increased public participation in each community in dental health education and treatment programs and to news of dental health accomplishments in individual cities and towns.

The editorship of the magazine is in the hands of Randolph G. Bishop, Editor; Paul E. Morgan, Managing Editor; and Cullison Cady, Associate Editor. Editorial offices are Room 934, Shoreham Building, Washington, D. C. NOTE: Review copies of *Dental Health* will be mailed upon request.

TWELFTH NEW ENGLAND HEALTH INSTITUTE

EDWARD A. McLAUGHLIN, M.D., Executive Chairman, has announced the Twelfth New England Health Institute to be held in Providence at the Biltmore Hotel, April 21 to 23.

The New England Health Institute is held under the sponsorship of the State Departments of Health of Maine, Vermont, New Hampshire, Connecticut, Massachusetts, and Rhode Island. The Sponsoring Committee consists of Edward A. McLaughlin, M.D., *Chairman*, Roscoe L. Mitchell, M.D., Charles F. Dalton, M.D., Travis P. Burroughs, M.D., Stanley H. Osborn, M.D., and Paul J. Jackmauh, M.D. Further information can be obtained from the Institute at 317 State Office Building, Providence, R. I.

NEW GRADUATE COURSE IN INDUSTRIAL HYGIENE AND MEDICINE

FRED J. WAMPLER, M.D., Professor of Preventive Medicine in the Medical College of Virginia, Richmond, has announced a graduate course in industrial hygiene and medicine cov-

ering one, two, or three months' duration.

The course will be offered by the Medical College of Virginia in coöperation with the Bureau of Industrial Hygiene of the Virginia State Health Department, the Industrial Commission of Virginia, the State Department of Education, and the medical departments of several industries in and around Richmond.

The course will cover field experience in the medical departments of two or more industries, work with the State Health Department Bureau of Industrial Hygiene in a survey of an industrial plant and in a laboratory, time with the Industrial Commission in study of compensation setup and problems, time with the Division of Rehabilitation of the State Department of Education and lectures, seminars, discussions and assigned readings on compensation laws, casualty insurance, morbidity and mortality reporting, statistics of industrial employment, special disease control programs in industries, labor's attitude toward medical programs, and the position of the industrial nurse in the medical program.

The tuition for the course will be \$50 for the first month, and \$25 for each succeeding month. Instruction will begin at any time after arrangements with the college.

PERSONALS

Central States

HENRY H. ASHER, M.D.,† who for the past 2 years served as County Health Officer in Sedgwick County, Kans., has taken over the position of Director of the Division of Local Health Services with the Kansas State Board of Health at Topeka.

FRANK J. HILL, M.D.,† of Bismarck

* Fellow A.P.H.A.

† Member A.P.H.A.

has been appointed acting State Health Officer of North Dakota, to succeed MAYSIL M. WILLIAMS, M.D., C.P.H.,* who has resigned to become District Health Officer in the New York City Department of Health.

B. RUSSELL FRANKLIN,† Sanitarian with the Ingham County Health Department in Michigan, has been appointed Chief Sanitarian of the Lorain County District Department of Health, Oberlin, Ohio.

HARRIET FULMER, R.N.,* resigned March 1 from the Rural Nursing Service of Cook County, Ill. Miss Fulmer, who at the time of her retirement was supervisor of nurses in the Public Health Unit, Chicago, has completed 25 years in this position.

THEODORE G. KLUMPP, recently appointed Secretary of the Council on Pharmacy and Chemistry of the American Medical Association, Chicago, has resigned to become President of the Winthrop Chemical Company, Inc., New York, N. Y.

ARTHUR B. REAM, M.D., of Mechanicsburg, Ohio, has been appointed Health Commissioner of Clermont County.

GEORGE M. SHINERS, M.D., Green Bay, Wis., has been appointed Health Commissioner of Green Bay.

WILLIAM E. SOVIK, M.D., has been appointed Health Officer of Campbell, Ohio, succeeding DR. EDWARD J. REILLY.

JOHN W. TURNER, M.D.,† formerly Health Officer of Marion County, Kans., has been appointed Health Officer of Sedgwick County, succeeding DR. HENRY H. ASHER.†

Eastern States

THOMAS J. BERGIN, M.D.,† Cos Cob, Conn., has been appointed full-time Health Officer of the town of Greenwich.

ALBERT E. CHILDS, M.D., of Litchfield,

Conn., has succeeded ELTON R. SKILTON, as Health Officer of Morris.

L. A. MACLEAN, M.D., D.P.H., recently of Massachusetts, has been appointed County Health Officer of Monongalia County, W. Va., and Director of the West Virginia Public Health Training Center at Morgantown. He succeeds DR. E. G. MCGAVRAN, now the Health Officer of St. Louis County, Clayton, Mo.

HUBLEY R. OWEN, M.D.,† Philadelphia, Pa., resigned as Chairman of the Council of Defense to give full time to his work as Director of Public Health.

ERNEST R. PENDLETON, M.D., has been appointed Health Officer of East Granby and Hartland, Conn., succeeding respectively, DR. ADOLPH VIETS, and DR. EDWARD A. GAYLORD.

PHILIP E. SCHWARTZ, M.D., has been appointed Health Officer of Portland, Conn., succeeding DR. JOHN R. TARRANT.

Southern States

BURTON F. AUSTIN, M.D.,† of Montgomery, Ala., Chief of the Bureau of Hygiene and Nursing of the State Department of Health, has been appointed Acting Health Officer of Alabama, pending a permanent selection to succeed the late JAMES N. BAKER, M.D., Montgomery.

RALPH L. BEST, M.D., Drumright, Okla., has been made Health Officer of Green County, with headquarters in Eutaw.

THOMAS O. COPPEDGE, M.D.,† Nashville, N. C., is now Health Officer of Nash County.

JESSE M. DISHMAN, M.D.,† of Princeton, Ky., Health Officer of Caldwell County, has been appointed Health Officer of Fulton County, succeeding LAYSON B. SWANN, M.D., of Paducah, who resigned to enter the army.

FREDERICK EBERSON, M.D., Ph.D.,*

formerly Pathologist and Director of Laboratories, Gallinger Hospital, Washington, D. C., has been appointed Medical and Research Director, National Drug Company, Philadelphia, Pa.

CORINNE S. EDDY, M.D.,[†] Centerville, Ala., has been appointed Health Officer for Bibb County. Dr. Eddy was formerly connected with the unit in Cleburne County.

FRANK L. LAPSLEY, M.D., Shelbyville, Ky., has been reelected Health Officer of Shelby County for a four year term.

LEO B. SKEEN, M.D., Sanatorium, N. C., has been named Health Officer of Iredell County.

VERNON W. TAYLOR, JR., M.D., of Madison, N. C., has been appointed Assistant Medical Director of the city hospital system of Winston-Salem, a position recently created because of an expanded program of public service.

WARREN T. VAUGHAN, M.D., of Richmond, Va., was awarded the honorary degree of Master of Science by the University of Michigan, Ann Arbor.

CLIFFORD E. WALLER, M.D.,* Silver Springs, Md., formerly Medical Director, U. S. Public Health Service, has been appointed Health Officer of the newly organized Health Department in Loudoun County, Leesburg, Va.

Western States

HARRY J. ANDERSON, M.D., of Corvallis, Ore., has been named Health Officer of Benton County, succeeding Dr. WILLIAM T. JOHNSON, who held the position for many years.

AMOS CHRISTIE, M.D.,[†] has been appointed Assistant Director of Medical and Health Service for the American Red Cross as announced by National Headquarters. Dr. Christie, who is

a member of the California State Board of Health, has been Associate Professor of Pediatrics at the University of California, San Francisco, from which institution he received his M.D. degree in 1929. He will be associated with ALBERT McCOWN, M.D., Dr.P.H.,* Director of Medical and Health Service.

CLARENCE R. E. LINDGREN, M.D., of Eugene, Ore., has been appointed Health Officer of Lane County.

EMIL E. PALMQUIST, M.D.,[†] Colfax, Wash., Health Officer of Whitman County, has been granted 6 months' leave of absence to study health administration at the University of Michigan, Ann Arbor. During his absence DR. PHILIP J. HOLABACH, Colfax, will be Health Officer.

JEAN G. ROBERTS, R.N., has been appointed Pacific Coast Nursing Supervisor of the Metropolitan Life Insurance Company Pacific Coast Head Office, San Francisco, succeeding Helen LaMalle who has retired. Mrs. Roberts has been Territorial Supervisor with the Metropolitan for the past two years.

RUSSELL H. WILSON, M.D., of Bremerton, Wash., has been appointed in charge of the Kitsap County Health Department, succeeding Dr. HAROLD M. GRANING, who was assigned to the Plague Laboratory of the U. S. Public Health Service at San Francisco.

Canada

G. W. MILLER, M.D., D.P.H., has been appointed Principal Medical Officer of the Royal Navy in India and of the Royal Indian Navy. Dr. Miller is a graduate of the University of Toronto and received his diploma in public health in 1936. He was formerly Deputy Public Health Commissioner with the government of India.

DEATHS

ALBERT E. AUSTIN, M.D., former Health Officer for 20 years of Greenwich, Conn., died on January 26 at the age of 64. He was President of the Old Greenwich Trust Company, a practising physician, and from 1939 to 1941 was Representative from the 4th Connecticut District in Congress.

H. C. BROWN, M.D., Health Officer of the City of San Jose, Calif., died on December 30, 1941.

SAMUEL W. LAMBERT, M.D., Dean of the College of Physicians and Surgeons of Columbia University, New York, N. Y., 1904-1919, and a former President of the New York Academy of Medicine, died on February 10.

PROFESSOR MERRILL J. MACK, Dairy Industry Specialist of Massachusetts State College, Amherst, died on February 9 following an operation, at the age of 39. Dr. Mack became a member of the Association in 1928 and a Fellow in 1933. He was identified with the Food and Nutrition Section.

Epidemiology of Tuberculosis in a Mental Hospital*

JOHN K. DEEGAN, M.D., J. E. CULP, M.D., AND
F. BECK, M.D.†

Hermann M. Biggs Memorial Hospital, Ithaca, N. Y.

EARLY in 1938, in reviewing the tuberculosis problem in Seneca County, New York, it was noted (1) that 23 per cent of all the cases of tuberculosis on the register were or had been employed at Willard State Hospital for Mental Diseases, and (2) that during the preceding 24 months there had been diagnosed among the employees of Willard State Hospital 11 cases of active tuberculosis of the lungs. These employees had been diagnosed following the onset of respiratory symptoms and were, for the most part, far advanced cases. This high incidence of tuberculosis in an employee group of approximately 725 was considered very significant and indicative of a situation requiring investigation, particularly because many of the afflicted had applied for compensation under the Workmen's Compensation Law. The New York State Insurance Fund reports that since 1935 it has expended more than

\$900,000 for medical and nursing care and compensation for 120 cases of tuberculosis which had been declared compensable among the 17,000 employees of the Department of Mental Hygiene.

Accurate data concerning the incidence of tuberculosis in the patient population at Willard Hospital was totally lacking, although known tuberculous patients were segregated in separate buildings. However, several of the afflicted employees had never worked on any tuberculous division and this fact caused considerable speculation concerning the incidence of tuberculosis in the general hospital population. A preliminary survey of the practices followed in diagnosing tuberculosis revealed a lack of trained personnel and equipment, and it seemed probable that there were many unrecognized active tuberculosis patients, exposure to whom was in part responsible for the tuberculosis problem in the employee group. This suspected high incidence of tuberculosis in the patient population was confirmed on reviewing the patient deaths at Willard from July 1, 1927, to June 30, 1938, when it was noted

* Read before the Epidemiology Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

† Now in the New York State Department of Health.

that tuberculosis was given as a cause of death in $8\frac{1}{2}$ per cent of all patients who died (198 of 2,321 deaths). The large number of tuberculous deaths prompted the investigation of the reported death rate from tuberculosis in other New York State mental institutions outside of New York City and the findings are presented in Graph I. The rate ranged from 0 per 100,000 in the Syracuse State School for Mental Defectives which houses mainly children and young adults to 1,497 per 100,000 in Kings Park Hospital. For the 3 year period 1937-1939 the tuberculosis death rate in mental hospitals was more than 12 times that of the general population of New York State, 618 per 100,000 versus 51 per 100,000. These startlingly high tuberculosis death

rates were found to have been prevalent for years, as presented in Graph II, which shows that during the period 1915 through 1939 the death rate in mental institutions was from 10 to 12 times that reported among the general population of the state.

A review of the literature confirmed the findings that the mortality and morbidity rates from tuberculosis in institutions for the care of patients with mental diseases are markedly elevated. Various investigators^{1,2} have commented on the overcrowding of mental patients and the carelessness of these patients in matters of personal hygiene as influencing the high incidence of tuberculosis in mental hospitals. The increase of tuberculous infection among patients according to the length of hos-

GRAPH I

DEATH RATES FROM TUBERCULOSIS (ALL FORMS) IN NEW YORK STATE AND IN STATE MENTAL INSTITUTIONS OUTSIDE OF NEW YORK CITY - - - (ANNUAL AVERAGE 1937-1939)

pitalization has also been demonstrated^{1, 3, 4} and the inference drawn that many patients contracted tuberculosis after admission to the hospital, there being ample opportunity for cross-infection.⁵ Several epidemiologists concluded that susceptibility to tuberculosis is not related to the type of mental disorder, except in so far as the mental disorder affects the length of time in an institution. Other reports^{5, 6, 7} have stressed the fact that employees working among the undiscovered tuberculosis cases in mental hospitals have contracted pulmonary tuberculosis.

INITIAL PATIENT SURVEY

At the onset of the survey attention was directed to the problem of cost. Adequate fluoroscopic facilities were lacking, making the use of x-ray films compulsory. Therefore, it was originally planned to do a preliminary "screening" by means of tuberculin testing and to x-ray the reactors only.

All patients except those known to be tuberculous received an intradermal test of 1.0 mg. of Old Tuberculin, 3,317 patients were tested and 2,872 (86.6 per cent) reacted.

The high incidence of tuberculous infection as indicated by the tuberculin reactor rate prompted us to x-ray the chests of the entire patient population rather than the reactors only. The additional cost was justified by the fact that films of known non-reactors could be of value: (1) as a check on the tuberculin test, (2) as a means of diagnosing non-tuberculous pulmonary and heart disease, and (3) in future epidemiological investigations should these patients subsequently develop tuberculosis.

During the course of the survey 3,407 adult patients (Table 1) between ages 17 and 91 were x-rayed, 14" x 17" celluloid films being used. Patients whose x-rays showed evidence of tuberculosis were studied carefully in an attempt to evaluate their dynamic status. Such

study included serial and stereoscopic films as indicated, and examination of the sputum when present for acid-fast bacilli. It is sometimes very difficult to get adequate sputum specimens from psychotic patients, and in many cases we were forced to judge activity by changes in serial x-rays or the presence of cavities. Our judgment of activity of the tuberculous lesions is based, in most cases, on about two years' observation.

We have classified our findings of tuberculous infection into four groups: (1) Active, (2) Inactive, (3) Apparently Healed, and (4) Calcification. In the Active group we included cases with cavities, evidence of progressive x-ray changes in serial films, positive sputum and a very few cases of exudative disease which appeared active on a single film. The Inactive group included those cases who appeared arrested or apparently arrested according to the National Tuberculosis Association Standards, while the Apparently Healed group comprises those cases of parenchymal fibrotic or fibrocalcific in-

filtration of little apparent present clinical significance. Solitary parenchymal or hilar calcified nodules or both were placed under the heading "Calcification."

Of the 3,407 patients studied we considered 76 (2.2 per cent) to have active tuberculosis; 157 (4.6 per cent) to be inactive; 110 (3.2 per cent) to be healed and an additional 351 (10.3 per cent) to show evidence of calcification. A total of 694 patients (20.3 per cent) presented x-ray evidence of infection, while 10 per cent showed evidence of reinfection type of tuberculosis, either active, inactive, or apparently healed. These totals included new admissions during the survey as well as new cases which developed during the same period. A study of 587 admissions during 1939 and 1940 revealed 17 cases of parenchymal tuberculosis (2.9 per cent), of which 7 were considered active, 2 inactive, and 8 apparently healed. In addition, calcification was noted in 52 patients (8.9 per cent).

Following the initial x-raying of all patients which was completed in the

early summer of 1939 suitable quarters in a building of modern construction were provided for the active cases. Likewise, the inactive and apparently healed cases were segregated so that they could remain under close observation. This segregation broke the contact with non-tuberculous patients and reduced the contact of employees to infectious cases to the lowest possible level.

SECOND PATIENT SURVEY

In 1940 x-ray films were repeated on 2,414 patients whose previous films revealed no tuberculosis, and it was found that 16 (0.66 per cent) new active cases had developed, 14 minimal, 1 moderately advanced, and 1 far advanced. It is probable that many of these cases had been in contact with open cases subsequent to their first film during the period when segregation of known active cases was in the process of development. The mental diagnosis in 13 of these 16 new cases was dementia praecox.

In the summer of 1940 there were retested 275 patients who had previously been negative to tuberculin and

again 1.0 mg. of OT was used. Of the 275 patients 130 (47.3 per cent) reacted 2 years after the first test and presumably had become infected following the first test.

In July, 1941, 163 patients who in 1940 had been tuberculin-negative were retested and 31 (19 per cent) had reactions, none of whom showed x-ray evidence of active clinical tuberculosis.

EMPLOYEE SURVEY

In view of the fact that 11 cases of active tuberculosis had been diagnosed in the employee group in 1936 and 1937 one of the prime objectives was to survey the employees in an attempt to discover unknown cases. Considerable effort from an educational standpoint was necessary before we received the support of the group and it was deemed practical to omit the tuberculin test and take only 14" x 17" chest films.

During the period September, 1938, to September, 1939, initial chest x-rays were made of 749 employees and staff members (Table 2). Clinical tuberculous lesions were found in 12 (1.5 per cent) individuals, 9 were minimal

in extent, 1 moderately advanced and 2 far advanced. The diagnosis of apparently healed pulmonary tuberculosis was made in 16 (2.0 per cent) cases, the majority of whom presented fibrotic or fibrocalcific infiltration giving the appearance of an obsolete process. Another 74 (9.3 per cent) employees revealed evidence of calcification of the parenchyma or hilar lymph nodes or both.

During the year September, 1939, to September, 1940, all employees had a second x-ray of the chest. Three employees (2 student nurses and 1 attendant) were found to have developed minimal tuberculous lesions in contrast to normal findings in the year previous. All 3 individuals were asymptomatic at the time of their diagnosis but had been in contact with known cases of tuberculosis among the patients.

DISCUSSION

A consideration of the findings in the various groups is pertinent. Over 50 per cent of the patients segregated in the tuberculosis pavilions previous to the survey were found not to have tuberculosis, the criteria for diagnosis in this group having been inadequate. The occurrence of significant cases of tuberculosis among the group of new patients tends to be lower than among the resident group and, while accurate statistical data are not available, it is our impression that the number of cases found increases with the duration of hospitalization.

From a mental standpoint it was noted that the highest case yield was in the more deteriorated patients where factors of personal hygiene and the general character of the surroundings would seem of importance. In the building containing this type of female patient 52 of 310 inmates presented evidence of reinfection type of pulmonary tuberculosis, while in the corresponding male building there were 56 cases among 287

patients. Dementia praecox was the diagnosis in 52 per cent of the patient population and this particular group yielded 67 per cent of the total tuberculosis cases found. Prolonged hospitalization in a tuberculous environment of these dementia praecox patients rather than a specific lack of resistance of this type of patient to tuberculosis is thought to be the dominating epidemiologic factor.

Segregation of the known cases of tuberculosis greatly reduced the health hazard but re-x-raying the previously negative patients plus the re-testing of previously tuberculin-negative patients in 1940 and 1941 revealed a high incidence of new disease and infection. From an epidemiological standpoint these results might have been caused by exposure to open cases of tuberculosis prior to the completion of segregation or exposure to new cases developing as a result of endogenous reinfection. To evaluate the problem annual x-ray surveys of the entire hospital population are desirable.

This problem was discussed⁹ with the authorities of the New York State Department of Mental Hygiene and New York State Department of Health, and subsequently a tuberculosis control program drawn up by those agencies¹⁰ for New York State Mental Hospitals. This program encompasses (1) a survey of mental hospitals by means of 4" x 5" x-ray film to determine the extent of the tuberculosis problem, and (2) necessary steps for control. The control measures are outline as follows:

Administrative:

1. Establishment of system of records to provide clinical, epidemiological, and statistical data.

2. Establishment of necessary prophylactic procedures and institution of a tuberculosis control educational program for employees associated with inmates, particularly in the tuberculosis wards.

3. Consultation service between the staffs of the Division of Tuberculosis of the State

Department of Health and the hospitals regarding all phases of the control and treatment program.

Patients:

1. Segregation of all known tuberculous cases and treatment thereof.
2. New patients to have chest x-ray alone or chest x-ray of reactors to tuberculin test.
3. X-ray reëxamination at end of one year to determine future needs.

Employees:

1. Study of employees with tuberculous lesions to determine clinical status.
2. Preëmployment x-ray examination of all new employees.
3. X-ray examination every 6 months of employees giving direct service to inmates and every 3 months of employees in tuberculosis wards.

As a result of an appropriation of \$45,000 by the Legislature of the State of New York, this program was recently inaugurated.

SUMMARY

Of the 3,407 patients studied initially, 343 showed evidence of reinfection type of tuberculosis, 76 of whom were clinically active; an additional 351 patients showed x-ray evidence of calcification either in the pulmonary parenchyma, the hilar glands, or both.

Re-x-ray within one year of 2,414 patients whose initial films were negative revealed development of active tuberculosis in 16 instances.

Segregation of known cases of clinical tuberculosis did not completely eradicate the infection hazard since 19 per cent of the negative reactors in the general population in 1940 became posi-

tive reactors within the year following such segregation.

Periodic x-raying of the chest of psychotic patients is of definite value in the early recognition of cases of tuberculosis and the control of this problem.

Of the 749 employees studied initially, 28 showed evidence of reinfection type of tuberculosis, 12 of whom were clinically significant; an additional 74 employees showed x-ray evidence of calcification either in the pulmonary parenchyma, the hilar glands, or both. Re-x-ray within one year of employees whose initial films were negative revealed development of active tuberculosis in 3 additional instances.

Routine x-raying of the chests of employees in contact with tuberculous patients is definitely indicated.

Study of Atypical Enteric Organisms of the *Shigella* Group*

ELIZABETH J. COPE, F.A.P.H.A., AND KEITH KILANDER
Detroit Department of Health, Detroit, Mich.

THE identification of the incitants of enteric disease presents slight difficulty when the microorganisms in question yield the biochemical and serological reactions that have become established for the various species. However, the problem of classification is not an easy one if the reactions of an isolated strain do not conform to the criteria that in the experience of different observers have been found to be definitely fixed for a given species. Scientific accuracy therefore imposes upon the conscientious bacteriologist the need for careful study of those microorganisms which do not completely fulfil accepted requirements for a precise classification.

Some recent experiences in the diagnostic laboratory of the Detroit Department of Health prompted the preparation of this report in order to discuss a number of strains which are seemingly identical and apparently belong to the *Shigella* group but which do not fulfil the biochemical and serological requirements for classification into any of the currently accepted groups of enteric pathogens. These strains were isolated from fecal specimens examined during the period from February, 1939, to August, 1941. The isolations were made from 116 specimens obtained from 83 individuals. Included in the group of persons who submitted these specimens

were patients with suspected or proven enteric disease, contacts, and food handlers whose clinical history revealed suggestive or definite reference to a previous intestinal disease.

The routine procedure employed in the examination of all fecal specimens is as follows: Two plates of MacConkey's are streaked in succession directly from the fecal mass using the same loopful of inoculum in order that the second plate may be less heavily seeded. One plate of SS agar is also streaked directly. Two bismuth sulfite agar poured plates are prepared, using as the inoculum 1 ml. and 5 ml. portions, respectively, of a 5 per cent emulsion of the specimen in physiological salt solution. In addition, approximately 1 gm. of feces is emulsified in one tube of tetrathionate broth. After incubation at 37° C. for 18-24 hours, transfers from this latter medium are made by streaking single plates of MacConkey's agar, SS agar, and bismuth sulfite agar. After incubation of all plates suspicious colonies are picked for transplant to Krumweide's triple sugar agar slants. The cultures on this medium which show acid reaction but no gas in the butt and no change on the slant surface are transferred to tryptone broth and, after 18 hours' incubation, tests made for motility as well as for indol production. At the same time transfers are made to tubes of broth containing the single sugars—dextrose, lactose, mannite, xylose, and dulcitol. Finally specific agglutinating sera are employed as indicated by these

* Read before the Laboratory Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

reactions. Difco dehydrated media were used throughout.

The organisms which are discussed in this report have the following cultural characteristics. They are Gram-negative bacilli, morphologically similar to those of the Eberthella-Shigella group. They are non-motile when freshly isolated although they may become motile on repeated subculture. Growth on phenolized agar, however, results in the reversion to smooth colonies with loss of motility. Colonies appearing on MacConkey's agar or on SS agar are colorless and transparent; while those on bismuth sulfite are green. Cultures on Krumweide's triple sugar agar slants produce acid but no gas in the butt and no change on the slant surface. Acid but not gas is produced when these strains are grown in media that contain only dextrose or mannite. No acid or gas is produced when media containing lactose, maltose, xylose, dulcitol, salacin, dextrin, or saccharose are employed. The production of indol is readily demonstrated in tryptone broth cultures. Utilization of citrate is demonstrated on slants of Simmon's citrate agar. Gelatin is not liquefied nor is litmus milk changed after 10 days' incubation. Growth on nitrate agar is accompanied by the reduction of nitrates to nitrites. Cultures grown on Kligler's iron agar or on agar containing lead acetate show no production of hydrogen sulfide. In plain broth cultures there is no evidence of pellicle formation except when the strain is in the rough phase. From analysis of these reactions, it appears that the utilization of citrate and possible development of flagella in the rough stage are the only cultural characteristics in which these organisms differ from those of the *Shigella paradysenteriae* Flexner group.

However, serological reactions show that this similarity is not as great as the biochemical reactions indicate. Antigenically, no resemblance to any of the

well known types of the enteric pathogens could be shown. None of the 116 strains were agglutinated by antisera prepared against *Shigella dysenteriae* Shiga, *Shigella paradysenteriae* Flexner V, W, X, Y, or Z, *Shigella sonnei*, *Shigella* sp. (Newcastle type), *Eberthella typhosa*, *Proteus morganii*, *Salmonella schottmuelleri*, *Salmonella paratyphi*, *Salmonella enteritidis* or *Salmonella cholerae suis*.

A strain which was isolated from an acute case of dysentery was arbitrarily selected as the type strain. Until the present it has been identified by the serial number of the specimen from which it was isolated, namely 1544. Using this strain as antigen, an antiserum was prepared. Organisms isolated from other sources, which were compatible biochemically were agglutinated by this serum to a titer of 1:160 or higher. On the other hand, this serum did not agglutinate antigens of *Shigella dysenteriae* Shiga, *Shigella paradysenteriae* Flexner V, W, X, Y, or Z, *Shigella sonnei*, *Shigella* sp. (Newcastle type), *Eberthella typhosa*, *Proteus morganii*, *Salmonella schottmuelleri*, *Salmonella paratyphi*, *Salmonella enteritidis* or *Salmonella cholerae suis*.

Sera were also obtained from four patients while they were acutely ill with dysentery. Examination of fecal specimens obtained from these patients revealed organisms that were biochemically and serologically similar to type strain 1544, but no other organisms of known pathogenicity were found. The sera from these four cases agglutinated the organisms which were isolated from their feces as well as the original type strain 1544 to a titer of 1:160 or higher. No positive agglutination could be obtained when these human sera were tested with the other antigens listed above. These serological experiments indicate that there is an antigenic similarity between the strains which are designated as group 1544, but that they

bear no antigenic relationship to any of the other established groups of enteric pathogens.

In order to ascertain whether the cultures under observation were stable or merely in a transitory phase, the following two procedures were employed. Twenty-four strains were transplanted daily, using tryptone broth and tryptone agar slants alternately. Once a week these cultures were transferred to plates of MacConkey's agar by streaking, and single smooth colonies were selected for a repetition of the alternate transfers to tryptone broth and tryptone agar. At the end of 4 months no antigenic or biochemical alterations were observed.

In further studies, three of the strains were injected intraperitoneally into mice. Eighteen hours after injection, cultures from the blood and peritoneal fluid of each mouse were made with successful recovery of the identical strains. Passage through a second series of mice and recovery of the organisms was made in the same manner. Studies of the bacilli isolated from the second series of mice revealed no variation in antigenic or biochemical characteristics.

COMMENT

The intent of this report is to present our findings in which there is demonstrated the apparent possibility of an atypical strain of shigella-like microorganisms occurring with marked fre-

quency in a community, and inviting a discussion on the significance of these findings. The isolation of similar organisms from 116 fecal specimens obtained from cases of dysentery, contacts, and food handlers occurred with such frequency as to draw attention to their possible importance as specific incitants of enteric disease. Biochemically these organisms resemble *Shigella paradysenteriae* Flexner. Antigenically they are distinct and apparently belong to a homologous group but are not related to any of the well recognized types of *Shigella*.

From the viewpoint of the bacteriologist one may ask how much effort should be expended in the study of strains which do not fulfil the requirements for classification into the established types. Moreover, should they be reported as newly identified subspecies or should this observed difference be disregarded? From the standpoint of the public health administrator, the question arises regarding the advisability of having the bacteriologist report such atypical strains to the physician. Finally, is the recording of the isolation of unclassified strains of epidemiological value?

ACKNOWLEDGMENT — The writers wish to express thanks to Dr. Joseph A. Kasper, Director of Laboratories, for his assistance in the preparation of this report.

The Time Factor in the Chlorine and Chloramine Disinfection of Contaminated Swimming Pool Water*

EMIL T. CHANLETT AND HAROLD B. GOTAAS

Former Research Fellow, and Professor of Sanitary Engineering, School of Public Health, University of North Carolina, Chapel Hill, N. C.; and Professor of Sanitary Engineering, School of Public Health, University of North Carolina, Chapel, Hill, N. C.

THERE have been comparatively few extended investigations of the several conditions which to some degree must affect our practices of swimming pool sanitation. There are two outstanding reasons why swimming pools have not received greater attention. First, there has been a lack of epidemiological evidence that the intimate contact of swimmers in an enclosed body of water constitutes a good opportunity for the communication of disease. Second, the technics of the treatment and examination of drinking water have been applied to pool water. It was with particular interest in the latter reason that an investigation of swimming pool sanitation was undertaken.

In meeting the demand for a treated water for pools the sanitary engineer drew upon his experience in treating drinking water. This was a reasonable approach, and in the main must be correct since there have been no reported epidemics in pools operated in accordance with the A.P.H.A. Joint Committee Standards, though the use of pools has greatly increased in recent years. Nevertheless, there is reason to believe that the wholesale carry-over from one to another does not make the same satisfactory results a foregone conclusion. A basic difference in the disinfection

problem of pool water from that of drinking water is that contamination is continuous with its use. Therefore the disinfection must also be continuous. This continuity of disinfection is sought by maintaining a residual of chlorine, the most commonly used swimming pool disinfectant, in the pool. Since the purpose of this chlorine residual is to minimize the hazard of pathogenic bacteria being passed from swimmer to swimmer, its disinfecting action should be as rapid as possible. The length of time it takes a disinfectant to kill bacteria is a function of its concentration. Since chlorine is irritating to human beings, there is an upper limit to the concentration which may be kept in the pool. In drinking water treatment, the bounds of time and concentration are not as narrow as they are in pool water.

In attempting to provide for a continuous disinfection more attention has been given to the problem of concentration than to the time of killing. The routine test for the concentration of chlorine in water is the rapid, simple orthotolidine method. This is a valuable tool in pool water control, but it has led to two results of doubtful character. It has tended to minimize the need for bacteriological examination and in so doing it has impeded the search for better methods of bacterial tests. Second, it has brought into vogue the use of ammonia in treating pool water. At the pH of swimming pool waters and

* Read before the Engineering Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

Figure 1—The Relations Between Bacterial Counts and a Constant Swimmer Load. Chlorine Residuals Below Effective Concentrations.

in the usual ratio of dosages, the ammonia and chlorine combine to form about equal amounts of monochloramine and dichloramine. The presence of chloramines in a pool makes possible the maintenance of higher chlorine residuals, as indicated by the orthotolidine test, without causing irritation to the swimmers. The orthotolidine reacts with the chlorine which is in combination with the ammonia as well as that which exists as hypochlorous acid. Yet it is solely the hypochlorous acid which is the rapid disinfecting agent. That means that the chlorine available for immediate concurrent disinfection is less than the orthotolidine test reading when chloramine is present.

In treating drinking water there are instances of conditions which make chloramine a highly desirable means of disinfection, but its carry-over into pool

water is questioned. On the face of the matter it appears to be fraught with the danger of yielding misleading readings of chlorine residual and of extending the time of disinfection. One of the objectives of this investigation was to determine whether the use of ammonia in swimming pools is a desirable procedure from the standpoint of efficient disinfection.

PUBLIC OUTDOOR POOL STUDIES

Making observations in two public outdoor pools in Durham, N. C., the relations among swimmer load, bacterial count, chlorine residual, and ammonia content were studied. The facilities and practices at these pools permitted the isolation of each factor and a step by step addition of each. The element of filtration did not enter as there was no filtration equipment. Figures 1, 2, 3,

Figure 2—The Relation Between Bacterial Counts and a Normally Varying Swimmer Load. Chlorine Residuals Below Effective Concentration.

and 4 present the noteworthy data. Each figure represents a series of samples taken through a morning or afternoon swimming period. Laboratory procedures were in accordance with accepted methods, closely adhering to Standard Methods. An outstanding difference was the incubation of bacterial plates, which were inoculated at the pool, for 36 hours rather than 24 hours.

Figures 1 and 2 show the resulting bacterial counts in a pool filled freshly with city water when the only factor was the swimmer load. No chlorine or ammonia was added at the pool. In the Figure 1 series the swimmer load was constant. A rapid and nearly constant increase in bacterial count was observed throughout the swimming period, the count having increased from 59 per ml. in the unused water to 1,280 per ml. at the end of 3 hours of use by a group of 40 children. Figure 2 shows the

bacterial variation due to a normally varying swimmer load. Excepting one observation a somewhat similar increase occurred. The count rose from 298 at the start of the afternoon period to 2,350 per ml. $3\frac{1}{2}$ hours thereafter, with a peak load of 100 children at the 2 hour point.

Figure 3 shows the effect of a single dose of chlorine in the form of calcium hypochlorite upon the bacterial counts resulting from a normally varying swimmer load. The chlorine dose, made just before the first swimmers entered the pool, was sufficient to produce a residual of 0.45 p.p.m. 30 minutes thereafter and to maintain it at that level or higher during the next 30 minutes. The chlorine produced an immediate decrease in count, and as long as sufficient residual remained, it prevented the count from increasing. When the residual had dissipated, the bacterial counts mounted in

Figure 3—The Relations Among Bacterial Counts, a Normally Varying Swimming Load and a Decreasing Chlorine Residual. Five Pounds of Calcium Hypochlorite Added Immediately after First Sample.

much the same way as those shown in Figure 2.

Figure 4 shows the bacterial counts during a normally varying swimmer load of rather small numbers when chlorine and ammonia had been added to the water by means of solution feeders. Addition was stopped at the start of the swimming period when the chloramine as chlorine residual was 0.35 p.p.m. The conditions of pH and ammonia to chlorine ratio were believed to be favorable to chloramine formation. The bacterial count rose immediately with the swimmer load in much the same way as in Figure 2, when no disinfectant was in the water and the swimmer load normally varying. The increase continued to a peak beyond the peak of the swimmer load. There then occurred a break downward in the bacterial count. This is suggestive of a delayed disinfection.

The character of this bacterial curve at the start of the swimming period as compared to that of Figure 3, when straight chlorine was available and the swimmer load normally varying, indicates a lessened concurrent disinfecting power in ammoniated swimming pool water as compared to unammoniated chlorinated water.

EXPERIMENTAL TANK STUDIES

The desire to observe the action of chloramines over a wide range of concentrations on the bacterial flora from swimmers' bodies, and to obtain some quantitative data on the suspected delay in disinfection led to the use of an experimental tank. The fact of inferior chlorine disinfection in ammoniated pools could be established by evidence that after use under a uniform swimming load for an equal period of time

a greater number of bacteria accumulate when ammonia is used than when it is not. These results are therefore based upon the proposition that a person following uniform hygienic habits could produce a reasonably constant bacterial loading in an experimental tank used for equal periods of time. The effectiveness of disinfectants in ridding the tank water of the contaminating bacteria can then be demonstrated by noting how the accumulation and subsequent disappearance curve differs from that obtained in the absence of any disinfectant.

It was found that a tank of 425 gallons of water was satisfactory for handling one swimmer. The desired conditions of chemical dosage would be set. The swimmer of uniform hygienic habits would then use the tank for a 5 minute period. Samples were taken

before entry, during use, and after use at frequent intervals. Standard procedures of analysis were adhered to closely.

The runs at chlorine residuals below 0.20 p.p.m. were made in order to observe the bacterial accumulation in the absence of chlorine or at concentrations believed to be below the disinfecting threshold of chlorine. In the absence of ammonia addition, the residuals were kept below 0.60 p.p.m. as it is the upper limit prescribed by the Joint Committee.⁶ Similarly, aside from one run made for comparative purposes, the residuals maintained when ammonia was added were between 0.7 p.p.m. and 1.0 p.p.m. This range is recommended by the Joint Committee in instances where ammoniation is practised. It was intended that the conditions of chlorine residual, ammonia content, pH, and

Figure 4—The Relations among Bacterial Counts, a Normally Varying Swimmer Load, a Variable Chlorine Residual and Increasing Ammonia Content. Chemicals Added by Solution Feeders and Recirculating Pump.

water temperature be as close as possible to those believed satisfactory, in order that the information obtained from the experimental tank could be readily related to conditions existing in pools.

Figures 5, 6, 7, and 8 present the

salient runs so arranged as to make comparisons clear. Figure 5 shows the plots of the 24 hour bacterial counts with a chlorine residual of zero compared to a residual of 0.13 p.p.m. The pH was 8.1 in each case. The ammonia content was 0.045 and 0.074 p.p.m. respectively.

The logarithmic character of the curve is evident. Both show slow decreases in bacterial counts. The small amount of chlorine had some effect as the counts decrease more rapidly in that case. At zero residual the count decreased from 245 to 140 per ml., a 43 per cent reduction, in 3 hours. At 0.13 p.p.m. residual the count decreased from 201 to 27 per ml., 87.5 per cent reduction, in the same time. Ammonia present was due to natural occurrence in water and to contribution by the swimmer.

Figure 6 shows the difference in bacterial accumulation and subsequent disappearance at a chlorine residual of 0.13 p.p.m. (ammonia 0.114), and a residual of 0.20 p.p.m. (ammonia 0.059). Under similar conditions of loading the count after 5 minutes of use reached 277 per ml. in the instance of the 0.13 residual compared to 37 per ml. in the case of a residual of 0.20 p.p.m. At the latter residual the count dropped to 4 per ml. within 10 minutes. At the 0.13 residual the count at 10 minutes was 224 per ml. At 1.5 hours it was 39 per ml. The magnitude of the areas under

the two curves is a measure of the efficiency of the two concentrations of chlorine in controlling the bacterial content of the water during the uniform swimmer loads and in the time immediately thereafter. A great increase in bactericidal velocity is noted in passing from a residual of 0.13 p.p.m. to one of 0.20 p.p.m.

Figure 7 shows the effect of the addition of ammonia. Both runs were made with a residual of chlorine of 0.50 p.p.m., and with similar conditions of loading. In one instance, no ammonia was added, in which case the incidental ammonia content was 0.073 p.p.m. at the start of the run, and 0.047 p.p.m. at the end. In the second instance, ammonia was added to produce a content of 0.255 p.p.m. In the case of no ammonia addition the count after 5 minutes of use was 6 per ml. Higher counts had existed after 1 and 3 minutes of use as is shown by the curve. With 0.255 p.p.m. of ammonia present the count after 5 minutes of use was 224 per ml. Five minutes after the swimmer left the water the count had dropped to 123 per ml. At 30 minutes

after exit the count in the tank of ammoniated water was 6 per ml., the same as the count after 5 minutes of use in the tank water to which no ammonia had been added.

The relative areas under the two curves indicate the relative effectiveness of the chlorine dosage and the chlorine-ammonia dosage. These areas may be expressed in units of bacterial minutes. That is, a weight in accordance with time of survival is assigned to each bacteria counted. The value of the ordinate multiplied by the value of the abscissa represents the area of a strip, which is in terms of bacterial minutes. By means of a planimeter the area under the curves was measured. In bacterial minute units, these are 72 in absence of ammonia, and 2,470 during ammonia dosage when the chlorine residual was 0.50 p.p.m., and a similar swimmer load was placed on the tank in both runs. This difference in bacterial minute units may be considered a measure of the exposure of fellow swimmers to the contaminating organisms washed and discharged from the body of one swimmer. Had a fellow swimmer been in the tank with the subject and remained in for a

period of 40 minutes, he would have been exposed to 2,470 bacterial minutes when the ammonia was added as against 72 bacterial minutes when no ammonia was added.

Figure 8 shows the results of two runs in which sufficient chlorine was added to ammoniated water to produce residuals of 0.90 p.p.m. and 0.95 p.p.m. In one run the ammonia was 0.275 p.p.m., a ratio of ammonia to chlorine of 1 to 3.3, and the pH was 6.9. In a second run ammonia was 0.226 p.p.m., a ratio of 1 to 4.2, and the pH was 7.1. The ratios of dosage and pH conditions are those commonly suggested for successful chloramine formation. The chlorine residuals are in the range recommended by the Joint Committee. The plots of the data show curves of a similar pattern which is decidedly logarithmic. The bacterial accumulation and subsequent disappearance are approximately the same. In the 5 minute swim period 159 bacteria per ml. accumulated at the 0.95 p.p.m. residual as compared to 170 per ml. at 0.90 p.p.m. In the 20 minutes following the swimmer's exit the count at 0.95 p.p.m. dropped to zero; at 0.90 p.p.m. to 3 per ml. In

terms of bacterial minutes, the area under the 0.95 p.p.m. curve represents 1,306 units, and the area under the 0.90 p.p.m. curve 1,200 units.

DISCUSSION OF RESULTS

In respect to the observations in the outdoor public pools the matter of the air being a source of bacteria must be considered. It was not possible to make a strict control run. However, data were obtained in a morning during which very few swimmers used the pool to which no disinfectant had been added. These indicated that the air was not an important source of bacterial contaminants. The studies under actual pool conditions gave evidence of a high correlation between swimmer load and bacterial counts, of a chlorine disinfecting threshold somewhere between 0.15 and 0.25 p.p.m. residual, and of a delayed disinfectant action when ammonia was added along with chlorine.

All of the data obtained from the experimental tank are dependent upon the reasonably constant bacterial loading in a uniform swim by the swimmer of controlled hygienic habits. Control runs were made before the series of disinfectant concentrations were begun. These indicated that a consistency of a remarkably high order could be expected. A difficulty that could not be circumvented was the natural occurrence of ammonia in the available water supply and the contribution of ammonia by the swimmer.

These uncontrollable sources of ammonia and the lack of a satisfactory specific test for chloramines cast some doubt on the distinction that must be made as to whether the disinfectant action in runs of low chlorine residual was straight chlorine or chloramine. Analysis by ratios is not satisfactory at the low concentrations of 0.13 and 0.20 p.p.m. of residual chlorine. Our knowledge of the chlorine, ammonia, and chloramine equilibrium at small concen-

trations is scant and our technics of analysis poor.¹ Decision on these must be withheld until our understanding is more complete.

In dealing with the higher residuals of chlorine and with the instances of ammonia addition there is no doubt that chloramines were formed. Figure 7 showing two runs where the sole difference was the addition of ammonia is offered as clear-cut evidence that there is a loss in concurrent disinfecting power in ammoniated water. At the higher chlorine residuals in the range recommended by the Joint Committee for use with ammonia, this loss and the consequent extension of the disinfecting time are demonstrated by the data from the experimental tank. A period of 15 to 20 minutes of contact was required to effect bacterial reductions of 98 per cent or better.

Though little data have been presented here on the ammonia contribution by swimmers, it is closely related to the problem under discussion. Data from these studies and other data obtained with the purpose of examining the significance of it in a recirculating pool indicate that swimmer contribution may reach amounts sufficient to produce unwittingly the conditions favorable to chloramine formation, but that the concentration of chlorine in the recirculating line at the point of dosage is great enough to impose by oxidation a ceiling upon the total ammonia content. A condition analogous to that studied by Weber and associates¹³ in demonstrating that the relation of ammonia to chlorine is a specialized case of breakpoint chlorination. It opens to speculation the possibility of utilizing some form of flash reading of chlorine residuals in swimming pools as suggested by Laux⁷ for controlling breakpoint chlorination of a public water supply.

Time does not permit an adequate review of the literature which while not extensive does afford corroboration and

contradiction on the points that have been made. Muzzey⁹ and Pringle¹⁰ agreed as to the direct correlation of load and bacterial count whereas Davis,² and Pearce and Sutherland (Davis²) did not. The latter investigators based their conclusions on spasmodic samples. In the matter of disinfecting threshold of chlorine the findings presented bore out Fenton (Mallman⁸). Stovall and associates¹² believed that 0.15 to 0.20 p.p.m. were adequate residuals for effective disinfection though their observations were made in a pool with a filtration system. The Joint Committee requires a minimum residual of 0.4 p.p.m. for straight chlorine treatment. As to the delayed disinfecting action of chloramines Hinman and Beeson,⁵ Gerstein,⁴ Schmelkes and associates,¹¹ and Weber and associates¹³ have established the matter in respect to drinking water treatment. Fletcher and Clark³ briefly examined the matter in regard to swimming pool waters. They found that a 20 minute contact period was required, but felt that it was a satisfactory disinfection method.

The findings of this investigation indicate that the benefits of an exceedingly speedy concurrent disinfection of all washings and discharges from swimmers is lost when ammonia is used in conjunction with chlorine. Experimental data not presented showed that it was possible to maintain straight chlorine residuals in water of 90° F. for reasonable periods. It is believed that under the most unfavorable conditions of high loads, sunshine and hot weather, modern chlorine dosing equipment in the hands of competent operators is capable of maintaining adequate straight chlorine residuals. It is believed that the inferior disinfectant action of chloramines outweighs the advantage of maintaining residuals which give creditable but meaningless orthotolidine readings. Therefore it is believed that the addition of ammonia should be discouraged.

SUMMARY

The results of a series of observations at two public outdoor pools and in an experimental tank under varying chlorine and chloramine dosages indicated the following:

1. There is a high correlation between swimmer load and bacterial counts.
2. There is a threshold of chlorine disinfection between 0.10 and 0.25 p.p.m. above which effective bactericidal action is obtained.
3. The addition of ammonia results in a loss in concurrent disinfection and consequent delayed disinfection which is pronounced at chlorine residuals as high as 1.0 p.p.m.

ACKNOWLEDGEMENTS — The authors gratefully recognize the valuable counsel of Dr. H. G. Baity, Department Head, in pursuing this investigation, and the diligent assistance of Robert Mac Connaughey in the laboratory work.

Delayed Birth Registration*

A. W. HEDRICH, Sc.D., F.A.P.H.A.

Chief, Bureau of Vital Statistics, Maryland State Department of Health,
Baltimore, Md.

THE tremendous increase in the demand for birth certificates for adults occasioned within the last two years by national defense has focused interest upon this problem. The Council of the Vital Statistics Section has requested that a brief report on the subject of delayed birth registration be made before the Section.

There are important reasons why a fundamental distinction should be made between registrations in infancy and registrations at adolescence or adulthood. In effect, a birth certificate is a statement of an individual, usually the attendant at birth, that a child was born to certain parents at a stated time and place. This certificate, if filed at or near the time of birth, enjoys exceptional prestige in the eyes of courts and other governmental agencies. This prestige derives from the legal presumption that the statements on the certificates are exceptionally trustworthy; first, because the maker of the certificate is likely to have observed and remembered the particulars of the birth correctly; and second, because there is ordinarily little motive for misstatement.

Statements made before there is a temptation for misstatement carry especial weight as evidence, so that they have acquired a special Latin designation, namely, "*ante litem motam*," meaning "before the litigation arose."

On the other hand, when a certificate is filed later in life, the foregoing pre-

sumptions no longer hold. We have abundant evidence that people become confused concerning birth dates and even birthplaces. Furthermore, adult registrations are usually requested because the registrant needs or desires to prove something; there is, therefore, frequently a powerful motive for misstatement of birth date or birthplace, and occasionally parentage. Experience having shown that unsupported registrations filed in adulthood are often incorrect, such registrations occupy in the eyes of the law and of governmental agencies, so low an estate that they too have acquired a Latin designation, namely, "*nunc pro tunc*," meaning "now, in place of then." To the cognoscenti, "*nunc pro tunc*" declarations are under a cloud of opprobrium.

There have evolved, therefore, within the last two decades, various special requirements for the delayed registration of births. These safeguards were occasioned by legislation in such fields as alien exclusion, child labor, veterans' pensions, poor relief, aid to dependent children, and, most important and recent, national defense.

In the last decade or so, a number of the border states, where the smuggling in of aliens became a problem, began to accept delayed birth certificates only after some sort of approval by a court. In 1933, a committee of this Section recommended that delayed registration through court procedure be made standard, but in the majority of states delayed registrations continued to be filed upon the certificate of an attendant, although in some cases supporting affi-

* Read before the Vital Statistics Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

davits were required. These affidavits too often were untrustworthy; nearly always they were, in effect, "self-serving declarations," and therefore of questionable evidentiary value. With the coming of the recent national emergency it became clear that more rigorous safeguards were necessary for delayed birth registration if the system was not to be thrown into discredit.

STANDARDIZING ACTIVITIES

Under the impetus of national defense activities, requests for delayed birth registrations increased tremendously during the spring of 1940, and there was a sudden awakening that co-operative action was imperative. As a result, in September, 1940, the U. S. Bureau of the Census, through initiative of Dr. H. L. Dunn, financed a meeting at Washington, D. C., of a committee appointed by President J. F. Blackerby, of the American Association of State Registration Executives. To this meeting were also invited the representatives of some twenty federal agencies. The conference first reviewed the evidentiary requirements of federal agencies for the establishment of place of birth, date of birth, and parentage in the absence of a certificate filed at birth. A set of standards was thereupon adopted by the Registrars' Committee which, after modification, was approved in principle by the federal agencies, by the Bureau of the Census, and in April, 1941, by the Conference of State and Territorial Health Authorities. Very recently the acting secretaries of War, Navy, and Commerce, at the request of Dr. Dunn, approved standards and recommended that they be used as a guide by state bureaus of vital statistics and by national defense industries.

In brief, the proposed standard method has the following features:

1. Delayed registration is defined as registration at or after the fourth birthday of a child.

2. The applicant is required to establish date of birth, place of birth, and parentage by three documents (baptismal, insurance, Bible, census, etc.) at least five years old. Two records will usually suffice if one was made before the fourth birthday. The requirements for proof of parentage have been eased somewhat by the Registrars' Association.

Two or more records are required, partly to save the applicant a trip or delay because too frequently one record has a flaw, such as an erasure, or an incorrect birth date or other error, or lacks proper authentication. A relatively low rating is given to affidavits of personal recollection, and to statements of physicians or midwives not supported by actual records.

3. A detailed abstract of the evidentiary records is to be given on the certificate and on copies thereof. This means, for example, that the abstract of a baptismal record will show the name and address of the church, the date of baptism and of birth, birthplace, and names of parents of the registrant as shown on the baptismal certificate. The standard certificate for delayed birth registrations shows this information in parallel column fashion, so that discrepancies can clearly be seen. Thus it is readily seen for example, whether a record gives the birth date explicitly, or only a statement of age on a specified date. Similarly, if one record states that an individual was born in Mississippi, and the second that he was born in Mexico, that conflict cannot escape notice.

Inconsistencies occur rather frequently, particularly on age statements. It would be thoroughly unsound to reject all cases which show any inconsistency; but it would be even worse to endeavor to conceal conflicts in records. To show the complete picture in the form of a detailed abstract is therefore only fair to the person who may use the record to make an important decision; the detailed abstract also relieves the registrar of embarrassing responsibility in doubtful cases, for he is in the position of merely setting forth the evidence, rather than of rendering a verdict. A court, governmental agency or other user of the certificate is thus permitted to make the decision for itself, as it should do in important cases.

OFFICE PROCEDURE

In general, the procedure of delayed registration, although somewhat variable from state to state, is likely to be about as follows: The registrant applies for a birth certificate. If no certificate is on file he receives a blank application or certificate form and a statement of the evidence required. Many applicants, particularly in the laboring group, require assistance in making out their forms and in locating evidentiary records. Therefore, a personal interview is frequently necessary, either in the state office or in a branch; for example, the county health office. This local assistance is important if the program is to work smoothly. Application and evidence are transmitted to the state registration office where the evidence is carefully reviewed, an abstract thereof entered on the certificate, copies issued as required, and the certificate is filed. The great majority of states make no charge for the registration but do make the usual charge of fifty cents to one dollar for the certified copy.

It is usually necessary to return to the applicant such evidence as family Bibles, baptismal certificates, and insurance policies. It is therefore useful as well as extremely inexpensive, to make a microfilm copy of the records. The film record of a single document usually costs less than two-tenths of one cent. As this device is relatively new in health department circles, it is of interest that an exhibit of microfilm equipment was arranged in the exhibit section at the Atlantic City meeting.

Manuals and other administrative helps have been issued by the Bureau of the Census and the Committee on Delayed Birth Registration of the American Association of Registration Executives.

ISSUES UNDER DEBATE

As the delayed birth registration procedure is relatively new it is to be ex-

pected—in fact it is probably desirable—that there be some variation in attitudes and practices in the various states. Thought on this subject has been so recent that it would probably do more harm than good to try to discourage initiative, experiment, and adaptation to local conditions.

The first point on which there is a considerable difference of practice is the question as to whether the evidence shall be evaluated and the decision as to registration made by a court or by the state registrar. At the present time a decision is made by courts or court clerks in the following states and possibly others: Vermont, New Jersey, South Carolina, Ohio, Nebraska, Texas, Michigan, Nevada, Oregon, and California. In some states the applicant has a choice of methods.

There is much to be said on both sides of this question, and possibly what is best for one state would not be best for another. The advocates of the court method point out that this procedure facilitates decentralization of work, as is necessary in large states; and that the employment of highly trained personnel by the state health department is thereby reduced. Opponents point out that the judges do not want the job and do not always perform satisfactorily. Moreover, say the opponents, the principal function of decentralization is to give advice and assistance to the registrant. This is not normally a duty of the judge, so that in the court procedure states it is frequently necessary for the applicant to employ an attorney at heavy expense. In California, the cost of delayed registration is said to be \$50 to \$100. In Nebraska it is \$2, but in that state the judges are raising the question of limiting petitions to attorneys. Moreover, some state registrars point out that if they must educate the applicant, search the files for a previous record, file the new certificate, and frequently educate the judge as to what is

necessary, the state registrar may as well do the intermediate job of evaluating the evidence. Therefore, although the court method has some strong adherents, as in Texas and Nebraska, and doubtless elsewhere, a majority of the state registrars do not favor it. In some states, however, where registrars have for financial or other reasons been unable to deliver the service demanded, the court procedure has been thrust upon them willy-nilly; in others, such as New York and New Mexico, the judges defeated legislation to establish the court method of filing delayed birth records.

A second subject of debate is whether the delayed registration certificate should contain the standard detailed abstract which cites *what* any record gave as to birth date (or age), birthplace, and parents' names, or whether, on the other hand, the certificate should only show by symbolic letters in a table *whether* a statement of specified type was made. Although the writer believes that the standard detailed abstract is advisable, even though it may add a cost of 20 or 25 cents per certificate, the question is clearly one in which experiment is desirable to determine whether the simpler procedure is practicable.

Finally, there is some discussion as to whether or not the delayed birth registration should attempt to establish identity. A proposal by the Bureau of the Census to place fingerprints upon the delayed registration certificate has been abandoned, but that Bureau and probably a majority of the registrars feel that the signature of the registrant should be upon the certificate, the in-

tention being that photostatic copies will show this signature and thus serve as a means of identification. To many persons, particularly to those who are not actually engaged in the work of registration, it will seem incomprehensible that a question should even be raised as to the desirability of establishing identity. Those who have reservations on this point, including the writer, point out that for the registrar to establish identity is an extremely difficult procedure, particularly at a time like the present. In the absence of ability to verify signatures more harm than good may be done by giving the "air of verisimilitude to a bald and unconvincing statement." Registrars know that when the registrant is at a distance the application and data for the certificate will very probably be filed by a member of the family who will not hesitate to sign the registrant's name to promote the prompt issuance of a certificate.

Therefore, without wishing to oppose the establishment of identity on the birth certificate, the writer wishes to emphasize that the subject should be approached as a field of experiment, and that the establishment of identity should not be imposed by mandate upon a registration system which is groaning under the effort to establish those data which are demanded of registrars by employers, and governmental agencies. Eventually, when this work can be done under less unfavorable conditions, it is quite possible that a system of identification should be linked not only to delayed birth registration, but to that far more conclusive document, the birth certificate filed in infancy.

The Functioning School Lunch*

MARTHA KOEHNE, PH.D., F.A.P.H.A.

Nutritionist, Ohio Department of Health, Columbus, Ohio

ONE cannot discuss the assigned topic without a preliminary statement about the function of the school lunch, whether provided by home, school or nearby restaurant, or the corner store. The noon meal selected by school children should be interesting to eat and should provide each day approximately one-third of the nutrients needed regularly for normal growth and for the maintenance of good health. Too often the school lunchroom is not a functioning part of the educational program of the school but is merely a convenient place where teachers and pupils can buy something to eat. Many home-packed lunches are so uninteresting that they are not eaten. Children who bring unsuitable lunches from home, or who eat undesirable types of lunches at home or elsewhere, and their parents need instruction to help them correct these conditions. Parents as well as pupils should be taught what foods are of special importance to children and why. Communities should see that provision is made for free lunches for indigent children, since this cannot be the direct responsibility of the school board.

The school lunchroom should provide the right kind of food for the children.

The first step in accomplishing this is to have a form of organization of the lunchroom that makes for maximum coöperation and efficiency. A school that undertakes the responsibility for serving

noon lunches should see that the lunchroom is under the control of the faculty and school board. Policies under which the lunchroom operates should be outlined by a lunchroom committee and approved by the school board. The lunchroom committee should be composed of at least two teachers (one of these being the home economics teacher if there is one on the staff), one representative each from the student body, parents and school board, and either a physician or nurse. The home economics teacher is the logical person to serve as manager, to see that these policies are carried out. She should, however, be given time in her schedule to devote to lunchroom management problems.

All over the country state nutrition defense committees are now being organized and these in turn are encouraging the organization, within each county, of county nutrition defense councils. One of the duties of these county councils would seem to be the formation of a county school lunchroom advisory committee to work with local lunchroom committees within the county. The county committee could also be of great help to school and community libraries in the selection of reliable and up-to-date books and pamphlets on the relation of food to health. The county advisory committees should be made up from the following types of persons: county health commissioner, public health nurse, home demonstration agent, home supervisor for farm security administration, dietitians and home economists who may be employed in the county by hospitals or colleges or who

* Read at a Joint Session of the American School Health Association and the Food and Nutrition and Maternal and Child Health Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

are married but willing to help solve county problems, and a representative of the parent-teacher group. This county committee may call upon various state representatives for advice and help: nutritionists and sanitarians of the state health department; nutritionists on the staff of the state agricultural extension service; state supervisors of vocational home economics of the state department of education; the director of school lunchroom projects for the Works Projects Administration; the state distributor of surplus commodities, and other members of the state nutrition defense committee.

The most successful school lunchrooms are those whose policies are based on knowledge of the food habits in the homes represented in the school. Cooperation of teachers, public health nurses, and parents is needed in securing this knowledge.

The second step in providing suitable foods for the children is to see that the type of service in the lunchroom is one that insures the selection of a satisfying meal. In many rural consolidated schools and urban elementary schools a plate lunch is the only food offered, except possibly a few supplementary foods for those with extra money and extra appetites. Children should not be allowed to buy these supplementary foods in place of items on the plate lunch. In other schools one or two plate lunches are offered as alternatives to free cafeteria choice. Other schools offer independent cafeteria choice only.

It is desirable that all school lunchrooms offer to pupils each day a special plate lunch at the lowest possible cost. When managers of cafeterias first introduce the plate lunch they often make the size of servings distinctly smaller than pupils get who purchase portions served "à la carte." They do this apparently in order to avoid loss of money. This, however, defeats the purpose of the plate lunch special, for there is

then no incentive to buy it, since it is not a bargain! School lunchroom managers should know the actual cost to them of servings of the foods they offer for sale, in order that, in planning plate lunch menus, actual money loss is avoided. The cost of the special plate should represent rock bottom minimum of profit, reliance being placed on volume sales to add to net profit. Commercial departments in high schools could profitably help in necessary cost studies.

The plate lunch plan of operation, with no cafeteria choice, reduces the number of foods to be prepared each day and enables the cooks to concentrate on making what is served unusually good. It permits wiser buying and more economical management. It makes possible considerable variety in menus from day to day and week to week, with less repetition. It teaches children what constitutes a well balanced meal and acquaints them gradually with a wide variety of foods.

When a school lunchroom serves children in the elementary grades, a plate lunch is of extreme importance. Small children have a great deal of difficulty both in seeing what is on a cafeteria counter and in deciding what they want. Sometimes teachers accompany first and second grade children to help them, but their judgment is not always sound. Seldom is help of any kind given to children beyond the second grade. It is of the greatest importance to help young children in their food choice if there is to be substantial progress in the development of good food habits.

The well planned plate lunch provides an excellent opportunity for teaching good food habits and greatly strengthens the health education program of the school. Teaching food habits out of supplementary readers is not effective. Neither can teaching food habits be effective without an intimate knowledge of the food problems of the pupils. If

the teacher knows the food habits of her pupils and wants to help correct them, she can accomplish a great deal, often more than any other one person. Teachers need guidance in this field of health education, however, and they need reliable reference material. They often need to correct their own food habits as well as those of their pupils. Knowledge of nutrition is not intuitive and instruction in nutrition is not yet a part of the required educational program in all teacher training institutions.

The third step in a program for supplying adequate school lunches is for the faculty, pupils, and parents to develop a consciousness of what is a suitable lunch for children, and for the manager to develop the ability to interpret this consciousness in the form of well planned menus that the lunchroom can afford to provide for the price the children can pay. Observations in many schools and knowledge of child food habits in many communities have led to the development of a standard pattern for a satisfactory plate lunch. This type of lunch has been found to fit the nutrition-health needs of a large percentage of school children and should be followed carefully in all feeding programs for needy children where lunches are provided without cost. The lunch planned along the lines of this standard pattern is quite universally known as a Grade A Lunch. It consists of:

Milk: One-half pint to drink, either as plain pasteurized milk or cocoa which has been made with milk, or one or two dishes rich in cheese or milk. Whether one or two such dishes should be included on a given menu, to replace milk or cocoa, depends upon the amount of milk represented by a serving of the food in question.

Vegetable or Fruit: One serving, raw whenever possible, with yellow or green varieties served frequently.

Main Dish: One serving, usually, of a hot food which has real staying or satisfying value. This dish should contain some meat or meat substitute.

Bread and Butter: Use at least as much dark bread as white bread. The white bread

that is used should be "enriched." When bread is served as a sandwich which contains meat or meat substitute, the hot dish need not be a meat or meat substitute type but may, for example, be a cream soup or thick vegetable soup.

Complete files of the menus served throughout the school year should be kept by every school lunchroom manager. Whether responsibility for the school menu rests with the home economics teacher, some other teacher, some committee, a WPA supervisor, or even with the cook, it is important that a complete collection of the menus be available for reference in succeeding years. Too often, with a change in personnel, there is nothing to guide new workers. Such menu records are of inestimable value if they are accompanied by brief comments, easily recorded on the back of each week's menus, as to the popularity of the foods served, their cost, suggestions for future modification, preparation difficulties, quantity prepared, source of recipes, etc.

Technics that have been used successfully in teaching children and communities lunchroom policies and the importance of good food habits:

The following suggestions are based on several years' experience serving as consultant to health departments and school superintendents on school lunchroom problems.

1. A plan found to work splendidly in acquainting the community with the problems of the lunchroom is that whereby the parent organization requires each of its members in turn to assist in the lunchroom one or more days each year. This develops a mutual understanding of the variety of problems involved.

2. A special parents' day may be planned each year to give parents an opportunity to survey the lunchroom and to learn something of the policies and problems involved in providing adequate lunches for their children. Parents should be encouraged to visit the lunchroom occasionally during meal service to see how the food is served and what it tastes like.

3. The lunchroom committee should sponsor talks to pupils, parents, and the community on child feeding problems, meal planning, etc., using the available professional personnel of the county and state previously mentioned.

4. One of the most effective methods of teaching the relation of food habits to health is to conduct simple animal feeding demonstrations which are closely followed by all of the pupils attending the school and by their parents. Manual arts classes may make the cages at very low cost; home economics classes may be responsible for the food; science classes may take care of the animals, plot growth curves, etc. Such demonstrations should be supervised by a person who understands the technic of animal feeding experiments and knows how to handle the animals. I cannot recommend too highly for school people interested in such methods of visual education a recent publication from the State College of Washington Home Economics Department.*

5. Home Economics classes can, at suitable times, prepare demonstrations of appropriate breakfasts and of desirable types of home-packed lunches, using foods that are economically possible for the parents to provide. These demonstrations should be shown in each classroom and, whenever possible, to the parent-teacher organization. In some schools elementary grades make special studies of breakfasts and lunches for school children.

6. The lunchroom will increase in popularity as the children in the school participate in helping solve its problems. Art classes can help in many ways to carry out ideas suggested by the lunchroom committee. Industrial arts classes may make many simple pieces of needed equipment and work on refinishing problems. English classes can just as easily write themes on food-health topics as on other topics. Drama classes often write and present clever nutrition plays. Commercial classes may learn valuable lessons in book-keeping, as well as in food costs, from working on lunchroom records. Various departments of the school, civics classes, hygiene classes, etc., should cooperate with the manager and health commissioner in making the school lunchroom the equivalent of a grade A restaurant in serving only clean, wholesome food.

7. In some schools a certain week in the school year has been called Vitamin Week or Nutrition-Health Week. Through a special

edition of the school paper, special assembly programs and attractive educational exhibits, a valuable educational program may be presented to the school and community. During this week, with the help of special groups of students, the grocers in the community may cooperate with special window displays of protective foods, or with an exhibit of a week's grocery order that would provide a family of specified composition with all needed foods in sufficient amount at minimum cost.

8. In one school the manager encourages pupils and teachers to submit menu suggestions and quantity recipes for any new foods that are included. When she is able to use the menu, she names it for the person who submitted it, and gives this person a free lunch on the day it is served.

9. In one school the popularity of the lunchroom is greatly enhanced by the fact that student helpers are chosen from the boys who are top notch leaders in the school.

10. If an elementary teacher has good food habits, she may increase her influence with her pupils by eating with them, and vice versa! In one school mothers reported that their children were demanding milk in their lunch boxes because their new teacher always brought milk in her lunch box.

11. Foods quite different from those generally used in a community should be introduced into the plate lunch very slowly. Free samples may even be given the first time the food is served. Classroom teachers should teach the value of new foods in advance of their inclusion in plate lunch menus.

Some of the objectionable dietary practices followed in some schools and how they may be controlled:

Sale of Candy—This is frequently sold in school lunchrooms in order that profit from its sale may offset losses from the poor sale of other food; or it may be sold in other parts of the building by groups of students who wish to raise money to support some legitimate school activity. Candy supplies chiefly calories and sweet flavor and is a non-essential. The regular use of food containing such a high concentration of sugar is also an important factor in the appalling incidence of dental caries among school children.

Sale of commercial fruit beverages and soft drinks—These contain sugar in

* Todhunter and Andes. *Nutrition Experiments for Classroom Teaching*. State College of Washington, Pullman, Wash. Price, \$25.

varying amounts; from practically none to usually not over an ounce of fruit; often citric acid to improve the flavor; and much water. They contribute little to the nourishment of the child.

Sale of many "penny snatcher" foods—These include potato chips, pop corn, crackers, pretzels, cookies and cakes.

All of these types of foods divert the child's meager lunch money from the purchase of needed nourishment. The average child has not over 10 cents for his whole noon meal. Every penny of this amount that is spent unwisely is spent at the sacrifice of some of his daily food needs. What measures may be taken to eliminate or greatly reduce the sales of such foods?

Some courageous school superintendents forbid all who cannot go home for lunch from leaving the school grounds during the school day, and thus minimize the possibility of patronizing corner stores. To carry out this program successfully, the superintendent must have an equally courageous school board and the sympathetic coöperation of the parents. In some communities there are ordinances forbidding vendors of soft drinks and "penny snatcher" foods from selling their wares within 500 feet of the school grounds.

In schools where these supplementary foods have long been sold and where antagonism might be created if they were suddenly withdrawn, their sale has been discouraged with the full understanding and coöperation of the parents, in the following manner: Meal tickets are sold at from 10 to 20 per cent reduction in price, as an inducement to parents to provide them for their children. These tickets cannot be used in

the purchase of candy, soft drinks, and other types of foods discussed above. The children must have cash in hand to pay for all such articles and the school is justified in making a much higher profit from their sale than from the sale of foods that are necessary to make a nutritionally adequate meal. This method also greatly reduces purchases at nearby stores and puts the responsibility squarely on the shoulders of the parents who provide their children with cash instead of meal tickets.

SUMMARY

We have discussed methods for developing policies under which school lunchrooms should be operated, and have indicated what persons can make contributions to a strong school lunch program. Various forms of food service are outlined and the many advantages of the simple plate lunch, or of the plate lunch special, are presented, together with the generally accepted pattern for the Grade A lunch. Many suggestions are offered for making the lunchroom and the noon lunch eaten by the children an integral and vital part of the health education program of the school. There is also a discussion of some of the undesirable dietary practices followed in many schools.

In conclusion may I suggest that, where an approved lunchroom can be developed, careful studies be made by the teachers and health department personnel of the effect of this program on the continuous growth record of the pupils, and on their absence records and progress in school. I believe that valuable support for such a program can thus be obtained.

Epidemic Influenza*

Epidemiological, Clinical, and Laboratory Aspects of the
1940-1941 Outbreak in St. Louis

S. EDWARD SULKIN, PH.D., F.A.P.H.A., JOSEPH F. BREDECK,
M.D., DR.P.H., AND D. DAVID DOUGLASS

*Research Bacteriologist; Health Commissioner, and Research Assistant,
St. Louis Health Division, St. Louis, Mo.*

IT is the purpose of this paper to report the results of virus neutralization and complement-fixation tests on acute and convalescent-phase serum specimens from patients with epidemic influenza, and to correlate clinical, laboratory, and epidemiological observations. Similar analyses were made with specimens obtained from persons with acute non-influenzal respiratory diseases in an effort to differentiate true influenza from its imitators. Several institutional outbreaks afforded an excellent opportunity to study the disease in its various aspects, and to ascertain the practicability of laboratory methods now available for the study of this disease.

Although influenza was made a reportable disease following the epidemic of 1918, statistical data pertaining to its prevalence are not accurate because of inadequate morbidity reporting; nevertheless, an attempt is made to indicate chronologically the movement of the epidemic of 1940-1941 in the United States.

According to the weekly reports of the U. S. Public Health Service, an unusual incidence of acute respiratory infections was reported in California during the last week in November, 1940.

This epidemic reached its peak in California during the week ending December 14. The next week peaks in reported cases were reached in the states neighboring California, and by the end of the month the disease had spread into the South Central states and North Central regions. As the number of cases on the West Coast declined, the incidence in the South Central regions continued to increase. The St. Louis peak was reached by January 11, 1941, and within two weeks the epidemic had reached Ohio, Pennsylvania, and some of the New England states. The number of cases reported by the East Atlantic and Southeastern states reached a peak at this time while the Mountain and Pacific regions, where the epidemic started, continued to show a sharp decline. By the week ending February 1, 1941, decreases in the incidence of influenza were reported from all geographic areas except the Middle Atlantic and some of the North Central states. In various sections of the United States recrudescences were reported after an interval of several weeks. An institutional outbreak occurred in St. Louis several weeks after the city-wide outbreak had subsided.

Shortly after the outbreak in California, Dr. B. P. Brown, State Director of Public Health, reported that the epidemic was due to infection with the Type A influenza virus. Soon after the

* Read before the Laboratory Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

St. Louis peak, we found that the Type A virus was the cause in this city, and within a few weeks Dr. Morris Schaeffer, of the Bureau of Laboratories of the New York City Department of Health, stated in a personal communication that human influenza Type A virus was isolated from washings obtained from cases occurring in Letchworth Village, New York.

An interesting feature of the nation-wide outbreak was the speed with which it spread throughout the country, traveling from the West Coast to the East Coast in less than two months. The course of the present outbreak resembled that of previous epidemics of 1928-1929 and 1932-1933. The major epidemic of 1918-1919, on the other hand, began in the New England states and traveled westward and southward.

Epidemiologically and clinically the 1940-1941 outbreak of epidemic influenza in St. Louis resembled those which have occurred repeatedly since the great pandemic of 1918-1919. The epidemic, which was quite explosive in character, started the week ending December 21, 1940, and continued until the end of February, 1941. A total of 120 patients were studied, including 70 white males, 25 white females, 24 colored males, and 1 colored female. The ages ranged from 6 to 64 years. Data concerning age, sex, color, date of onset, date of confinement,

duration of illness, clinical findings, and clinical pathological findings were obtained by means of questionnaires.

The clinical findings in the cases proved to have epidemic influenza were as follows: The onset of the disease was abrupt, with predominating symptoms of fever, headache, generalized body aches, prostration, slight throat irritation, and persistent dry cough. No un-

- Cases of Epidemic Influenza
 - Upper Respiratory Infections other than Influenza

FIGURE 1—Frequency of clinical symptoms in proven cases of influenza and patients with acute non-influenzal respiratory infections

usual findings were observed on physical examination. The fever usually subsided in 3 to 5 days. A high percentage of the cases showed uniformity of symptoms, and complications were relatively infrequent. The average duration of the symptoms was about 5 days. The height of the pyrexia varied from 100° F. to 105° F. and the duration of the fever was about 3 to 4 days. The disease was characterized by a prolonged and uneventful convalescence, the patient appearing pale and indisposed for several days without symptoms except for a slight cough and a feeling of lassitude.

The frequency of various clinical findings among the proven cases of influenza have been compared with those of patients with acute non-influenzal respiratory infections. The differential clinical features are presented graphically in Figure 1. It will be noted that respiratory complaints appear to be prominent in the non-influenzal cases, whereas they are minimized in the true influenzal patient. The frequency of the various symptoms in the influenzal group bear a striking resemblance to those reported by Horsfall and associates in their study of the 1939-1940 outbreak in Yorktown Heights, New York.

That the 1940-1941 outbreak of influenza was relatively mild is suggested by the infrequency of complications. During the epidemic period only 85 cases of broncho or lobar pneumonia, complicating upper respiratory infections, were reported to the Pneumonia Control Service of the Health Division, and only 25 deaths attributable to pneumonia, preceded by upper respiratory diseases, were reported to the Registrar of Vital Statistics. These figures are only slightly higher than those of previous years.

Conflicting reports have appeared in the literature concerning the value of the leucocyte count as an aid in the diagnosis of epidemic influenza. Since the

leucocyte counts available for analysis in the present study were made by the physicians submitting cases for investigation, they are subject to considerable variation. Of the proven cases of influenza, 28 per cent had a leucocyte count over 7,000 per cu.mm. and the count averaged 6,044 per cu.mm. disregarding the day of the disease. When the count was made during the first 3 days, the average number of cells was 5,463 per cu.mm., while an average of 7,883 cells was found if the counts were made during the 4th, 5th, or 6th day of the disease. Of the proven non-influenzal cases, 93 per cent had a leucocyte count over 7,000 cells per cu.mm. The results are summarized in Figure 2. Similar observations were reported by Francis, and more recently by Reyersbach, Lenert, and Kuttner. These observations suggest that low white blood cell counts or the absence of a definite leucocytosis during the

early days of the disease is significant.

"Garglings" were obtained from a few representative patients within the first two days after the onset of the disease. A few ml. of sterile infusion broth were dropped into the nostrils of the patient, followed by gargling approximately 30 ml. of broth. The washings were immediately frozen and transported to the laboratory.

A filterable infectious agent, later identified as human influenza virus, was recovered from throat washings by direct inoculation into mice and on the allantoic membrane of developing chick embryos. Details of some of the mouse and chick passages are presented graphically in Figure 3. The identity of the

virus producing pulmonary lesions in mice and macroscopic changes on the allantoic membrane of the chick after the 4th serial passage was established by means of a protection test with a sample of convalescent-phase serum known to contain both complement-fixing and neutralizing antibodies. The virus was found to be immunologically related to Type A strains of human influenza virus (PR-8 and W.S.) isolated during previous influenza epidemics. The recovery of virus by serial passage in mice and developing chick embryos, without resorting to preliminary passage in the ferret, corroborates the reports of other investigators.

The results of parallel neutralization

and complement-fixation tests on acute and convalescent-phase serum specimens from 27 patients with influenza are presented in Table 1. The acute-phase blood specimens were obtained an average of 3.5 days after the onset of the disease, while the convalescent blood sera were obtained, on the average, 18 days after the onset of the disease. The mean neutralizing antibody titer of the acute-phase sera was 1:6 and the mean titer of the convalescent sera was 1:93. The mean complement-fixing titer of the acute-phase sera was 1:3.8 and the mean titer of the convalescent sera was 1:38. A significant increase in complement-fixing antibodies was demonstrable in the con-

valescent-phase serum specimens from all but one of the patients. Virus neutralizing antibodies were demonstrated in this serum specimen, and influenza A virus was recovered from throat washings of this patient. Complement-fixation tests on serum specimens from 5 of the patients, using lung suspensions from mice infected with influenza B virus (Lee strain) as the antigen, were conducted by Dr. Edwin H. Lennette of the Rockefeller Institute. None of the sera tested with the Type B influenza virus showed an increase in specific complement-fixing antibodies in the convalescent-phase serum specimens as compared with the acute-phase specimens. Specific complement-fixing anti-

— Not done.

bodies against the Type A influenza virus were demonstrated in the corresponding sera. In interpreting the results of the complement-fixation tests an increase in titer of twofold or greater was considered significant evidence of an antibody response. In our experience, the level of antibodies indicative of epidemic influenza was found to be near a titer of 1:16 in terms of the original dilution of the serum.

The results of complement-fixation tests on two blood specimens from each of the patients with epidemic influenza and acute non-influenzal respiratory diseases are summarized in Table 2.

however, some differences occur. Respiratory complaints appear to be common in the non-influenzal cases, whereas, they are minimized in the true influenzal patient. Low white blood cell counts, or at least the absence of a definite leucocytosis during the early days of the disease, is of diagnostic significance in influenza. Because of the difficulty in differentiating true influenza from other respiratory diseases, confirmation of clinical diagnosis must depend upon the use of laboratory aids, especially since the presence of an epidemic in a community may color the diagnostic viewpoint. It has been the purpose of this

TABLE 2

Results of Complement-fixation Tests with Epidemic Influenza Virus on Two Blood Specimens from Each of the Patients with Upper Respiratory Infections

Cases	Number of Cases	Acute-Phase Blood Mean Titer	Convalescent- Phase Blood Mean Titer	Per cent of Cases with Increase in Titer
Epidemic Influenza	54	1:3	1:47	98.14*
Other Upper Respiratory Diseases	24	1:7	1:8	12.54†

* One patient's serum showed increase in neutralizing titer but no increase in complement-fixing titer.

† Convalescent serum specimens obtained during the epidemic period from 3 patients showed slight rise in complement-fixing antibodies.

Of the 54 cases of epidemic influenza studied, 98 per cent showed a significant increase in complement-fixing antibodies in the convalescent-phase serum specimen. The mean titer of the acute-phase serum was 1:3 and that of the convalescent serum was 1:47. The convalescent-phase serum specimens from 3 of the 24 patients with acute non-influenzal respiratory infections showed an increase in complement-fixing antibodies. Since these blood specimens were obtained during the epidemic period it is possible that the cases were contacts or had coexisting influenzal infections.

The clinical symptoms accompanying the early stages of epidemic influenza are common to numerous other respiratory diseases; as the disease progresses,

investigation to correlate laboratory, clinical, and epidemiological findings to enable the practising physicians to dissociate true epidemic influenza from the mosaic of other respiratory infections.

During the outbreak under investigation, human influenza A virus was isolated by serial passage in mice and developing chick embryos without preliminary passage in the ferret. The virus was found to be immunologically related to other Type A strains of human influenza virus isolated during previous influenza epidemics.

Although the most conclusive evidence of influenzal infection is available when virus has been recovered from throat washings of a given patient and an increase in neutralizing and complement-fixing antibodies demonstrated in

the convalescent serum of the same patient, correlation of laboratory and clinical findings show that the serological procedures now available are applicable even in the absence of virus recovery. Furthermore, antigenic differences which may exist between the various strains of the same virus type do not interfere with the use of the serological tests in the diagnosis of this disease.

Correlation of clinical findings with results of the neutralization and complement-fixation tests are presented. The authors believe that the complement-fixation test is a simple specific serological procedure which does not require highly trained personnel or special equipment. The practicability and accuracy of this test have been emphasized by other investigators. The neutraliza-

tion test, on the other hand, is a more complicated and delicate procedure. It is suggested that public health laboratory workers throughout the country familiarize themselves with the complement-fixation test for influenza in order to be prepared for future outbreaks.

ADDENDUM

Since this manuscript was submitted for publication additional *in vitro* tests have been described by Goodner (*Science*, 94:241, 1941), Roberts and Jones (*Proc. Soc. Exper. Biol. & Med.*, 47:75, 1941), and Hirst (*Science*, 94:22, 1941, and *J. Exper. Med.*, 75:49, 1942). Experiments are now in progress to determine the practicability of these tests as compared with those described in this paper.

Studies on Aberrant Coliform Bacteria*

LELAND W. PARR, PH.D., F.A.P.H.A., AND
HAROLD FRIEDLANDER

Department of Bacteriology, Hygiene, and Preventive Medicine, School of Medicine, The George Washington University, Washington, D. C.

NORMAL coliform bacteria dissimilate lactose with the prompt production of acid and gas. On the other hand, the aberrant coliform bacteria ferment lactose slowly, with acid production only, at low temperatures only, with partial gas production only, or even not at all,[†] and present many real problems.

Stuart, Mickle, and Borman¹ have suggested a grouping of these bacteria which marks a distinct advance in a difficult field. The present report is concerned with one of the four Stuart groups, namely,

GROUP III. "Papillae-forming coliforms—aberrant coliforms showing the type of dissociation evidenced by *Bacterium coli mutabile*, but not confined to the genus *Escherichia*."

We agree fully with Stuart and co-workers that: "The papillae-forming group will be detected only infrequently in routine coliform estimates in which gas production is used as the criterion for their presence and the anaerogenic group will not be detected at all. However, these two groups may be highly significant because of their frequent association with gastroenteritis and genitourinary infections." It is obvious that any new light on the behavior and relationships of these organisms is

significant for sanitary bacteriology.

Beginning March 15, 1940, the "bacteriological autobiography" of one of us,³ previously reported in some detail was resumed. By March 11, 1941, 25 additional fecal specimens had been examined. A small portion of each sample was suspended homogeneously in 30 ml. of saline and plated in varying amounts on at least three Endo's agar plates. From each of the resulting sets of plates colonies were picked for study. It was noted that colorless colonies typical for *Bacterium coli-mutabile* were present in every one of the 25 specimens and that on only 15 sets of plates were any colonies present of the type commonly attributed to *Escherichia* or *Aerobacter*.

In the case of each of four of these samples showing practically pure cultures of aberrant coliform bacteria 100 well isolated colonies were fished to phenol red lactose broth. At the end of 48 hours 361 of the fishings either had not shown evidence of fermentation at all (33), had produced only acid (61), or had given rise to an acid reaction with just a trace of gas (267). At the end of 7 days, 2 were "growth only," 28 "acid only," 237 "acid with trace of gas," and only 133 showed acid and normal gas production. Thus, even after 7 days' incubation, 267 of the 400 colonies picked would have failed to give a positive presumptive test.

Realizing that such procedures are too crude for any significant results to be deduced because the colonies may not

* Read at a Joint Session of the Laboratory and Engineering Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 15, 1941.

† Parr² includes certain lactose negative organisms in the coliform group under the designation of "para-colon bacteria."

be pure and because of uncertainty of colony relationship, we determined to see what would be the reaction in series of lactose broth tubes if colonies from pure cultures of Group III aberrant coliform bacteria were used. We had available for study a number of such strains obtained from colleagues at Brown, Maine, Kansas, Tennessee, and from our own work. Pure strains of papillae-forming coliform bacteria were plated from broth culture to Endo's agar. From each resultant growth, at 24 hours, 10 colonies were picked at random to 10 tubes of phenol red lactose broth. The 10 tubes were incubated at 37° C. and observed daily for at least 10 days before any tubes were discarded. Tubes showing acid production only, or partial gas production only, or growth only, were held for much longer periods of time, often 5 to 6 weeks. Whenever the purpose of the study demanded, plates were made from selected lactose broth tubes in the series and colonies again inoculated into lactose broth and observed.

Since the Group III aberrant coliform bacteria are slow fermenters of lactose, it is not to be expected that any lactose

broth tube inoculated from a colony will show acid and gas in 1 day, necessarily, or even in 2 or 3. One would expect, however, that when evidence of fermentation begins to appear it should do so in all 10 of the tubes inoculated in the series at approximately the same time. The original *inocula* used are, of course, unequal in quantity and this might occasion some slight differences, but on the assumption of stabilized and similar essential structure of the bacterial cells involved, such differences in appearance of acid and gas in the several tubes should be small and these differences should be haphazard and not correlated with other characters of the growths under observation.

Such, however, was not the case with the cultures tested. What did happen was that, after a lapse of time during which the only recording for all tubes was "growth only," certain of the tubes, usually from 1 to 4 of the 10, suddenly produced "acid and gas." The other tubes remained "growth only." If a tube showing the sudden, though late, fermentation was plated on Endo's agar, two types of colonies developed within 24 hours, the metallic red colony

characteristic of a prompt fermenter and the colorless colony characteristic of an aberrant coliform strain. The tubes which remained "growth only" at this stage eventually progressed to (1) acid production, or (2) the production of acid and a trace of gas, or (3) to full acid and gas production and retained this reaction until discarded, but they did not breed true, and if plated out, particularly before the broth was 10 days old, revealed only the colorless colony characteristic of the aberrant strain. In Table 1 are given the results in illustrative series for 2, 3, 7, and 10 day incubation intervals.

Having determined to our satisfaction that certain tubes in each series would in a few days give rise to a typical, though late, reaction and would yield two types of colonies on plating, we were interested in investigating the possibility that through selection one could derive lactose negative strains, very slow fermenters, cultures producing only acid, or cultures constantly producing only a trace of gas in addition to acid.

Regarding the first possibility it may be said that we have not yet encountered from the strains we have worked with a single lactose tube showing a reaction of "growth only" which did not at least progress to acid production if observed long enough. The data given below will show that at 10 days certain tubes are "growth only" but in every case acid, at least, was produced with a few more days' observation. We endeavored by selection to derive strains which would

(1) remain permanently lactose negative, or (2) ferment lactose very slowly. A series of sixty lactose tubes which had remained "growth only" for from 4 to 10 days was plated and from each plate 10 colonies were picked to lactose broth. At the end of 10 days' incubation, 8 tubes were "growth only," 184 were "acid only," 146 showed acid and a trace of gas, and 262 showed acid and full gas production. Each of the 8 "growth only" tubes eventually fermented lactose.

In our series a large number of tubes of lactose broth produced a reaction of acid only, and this reaction persisted for many of the tubes despite weeks of observation. Except for 2 tubes recorded by Robbins and Parr,⁴ not one of these tubes bred true. Eighty-five tubes in which the age was from 4 to 25 days and the reaction "acid only" were plated on Endo's agar and from each plate 10 colonies were picked to lactose broth. After 10 days' incubation at 37° C. the results were: 1 tube "growth only," 208 tubes "acid only," 398 tubes "acid, with a trace of gas," and 243 tubes, "acid and normal gas production."

A similar experiment was carried out for 74 tubes in which the reaction was normal acid with subnormal gas production. After 10 days' incubation the 740 tubes fell into the following classification: 2 "growth only," 64 "acid only," 400 "acid with a trace of gas," and 274 "acid and normal gas production." It should be pointed out that

TABLE 2

Distribution of Reactions After 10 Days' Incubation at 37° C. in "Selection" Series of Lactose Broth Tubes

Strain Tested	Number	Percentage of Tubes Giving Reactions Noted			
		Growth	Acid	Acid, Trace Gas	Acid and Gas
Growth only	60	1.3	30.6	24.3	43.6
Acid only	85	0.11	24.4	46.8	28.6
Acid, trace gas	74	0.25	8.6	54.1	37.0

many of the tubes which at 10 days showed "acid and normal gas production," produced that reaction only after several days delay and would have been missed in routine standard methods analysis. The results from these experiments are summarized in Table 2.

From these experiments it is obvious that cultures derived from aberrant coliform bacteria (Group III) do not readily (if at all) give rise through processes of selection to strains other than the two already well known, *i.e.*, the prompt and typical lactose fermenter and the original aberrant, "mutabile," or "unstable variant." Parr and Robbins have obtained authentic anaerogenic ("acid only") strains from such sources, but under conditions which suggest "mutation," and such instances are rare.

DISCUSSION

Our findings do not particularly simplify the problems certain aberrant coliform bacteria offer sanitary bacteriologists. On the other hand, we believe that it is shown that certain of these "slow-fermenters" have fully as much sanitary significance as normal coliforms. If organisms which sanitary procedures will not reveal are truly fecal in nature it may be questioned whether our procedures are entirely adequate. Our safety has been assured by the fact that most significant pollutions are communal in nature and practically always include feces containing normal coliform bacteria. The occurrence of aberrant coliform bacteria is, however, by no means uncommon, even in the healthy, as has been pointed out repeatedly by many writers. We fully agree with certain writers that some of the aberrant coliform bacteria represent only harmless forms of the field and granary. We know that others derive from mammalian feces and often from individuals more or less ill. Can these two groups be differentiated?

We believe, further, that whenever

possible all cultures appearing to be aberrant in nature should be checked by the method of multiple subculture which we have described above. If most of the Group III aberrant coliform bacteria will break down as we have described, there is in multiple subculture a method of checking suspicious isolations which may be of value. Further experimentation designed to bring out differences between significant and non-significant aberrant coliform bacteria is highly desirable.

CONCLUSIONS

Data are presented on papillate aberrant coliform bacteria of the *Bacterium coli-mutabile* type showing that in multiple, serial subculture these strains exhibit a partial "mutational" activity in lactose broth. About one-fourth of the tubes inoculated show slightly delayed but otherwise normal lactose fermentation. The populations in such tubes are shown by plating to be of two kinds: the normal coliform, and the aberrant coliform, having similar reactions save for lactose fermentation. The balance of the tubes of lactose broth inoculated in any series progress slowly to the production of acid or of acid and variable amounts of gas, but such tubes do not breed true.

It has been impossible by ordinary methods of selection to isolate and preserve strains showing no fermentation of lactose, acid production only, or acid and subnormal gas production only.

It is believed that cultures showing aberrant reactions should be studied in multiple subculture if their nature is to be best understood.

The importance of distinguishing between significant and nonsignificant aberrant coliform bacteria is stressed.

Simultaneous Administration of Diphtheria Toxoid and Pertussis Vaccine in Young Children*

LOUIS W. SAUER, PH.D., M.D., AND WINSTON H. TUCKER,
PH.D., M.D., F.A.P.H.A.

*Assistant Professor of Pediatrics, Northwestern University Medical School,
Chicago, Ill.; and Commissioner of Health, Evanston, Ill.*

THE ability of the body to develop protective substances after two or more antigens are injected, either simultaneously or mixed in the same dose, opens a wide field in preventive medicine. Protection of children against diphtheria and tetanus by the administration of mixed diphtheria and tetanus toxoids has been demonstrated within recent years. Bordet,¹ Director of the Pasteur Institute in Brussels, reported in 1936 on the injection of infants and children against whooping cough and diphtheria by the use of a mixture of *Hemophilus pertussis* vaccine and diphtheria anatoxin (toxoid). Ramon, Director of the Pasteur Institute in Paris, and Debré, the pediatrician, collaborated with Bordet. Three hypodermic injections were given at 3 week intervals as Zoeller² had recommended for diphtheria immunization. The third dose was fortified by the addition of appreciably more pertussis organisms. Bordet concluded: "It seemed logical to attempt immunization against these two diseases at the same time, because it is at the same period of life when they are most likely to occur in severe form."

At the Evanston Health Department immunization clinic, a total of 1,586 Infant Welfare clinic children between the ages of 8 and 24 months were injected with *Hemophilus pertussis* vaccine prior to October, 1938. The pertussis vaccine † was injected at 3 week intervals after the 8th month of life, because it was found that complement-fixation tests, made two or three months after the final injection, showed a higher incidence of 3+ and 4+ reactions when this procedure was followed than when the injections were given at weekly intervals, or earlier than the 7th month of life. Likewise when the retest was performed a week after the final injection, a higher complement-fixation was found in cases where there had been a 3 week interval between injections than in those where there had been a weekly interval. The intermediate strength vaccine (15,000 million organisms per ml.) was preferred, because it was less voluminous than the original 10,000 million, and local reactions were less than with

† Pertussis Vaccine Immunizing (Sauer), authorized by Northwestern University Medical School, is prepared in a biological laboratory, according to detailed specifications.⁴ The vaccine is not washed, as it contains no animal protein. Each lot is examined and approved by the Whooping Cough Research Laboratory of Northwestern University Medical School before it is released.

the 20,000 million concentrations. Approximately 4 months after completion of the pertussis immunization, three diphtheria toxoid (plain) injections were given at 3 week intervals and, about 6 months later, smallpox vaccination was carried out. Pertussis vaccine was always given first because, as Hektoen and Lovett³ pointed out: "Of all contagious diseases, whooping cough is the most likely to affect the youngest members of the family; and herein lies its chief danger. Whooping cough, like smallpox, diphtheria, and scarlet fever, may often be prevented if an ample dosage of potent whooping cough vaccine is injected into infants over 7 months of age, sufficiently long before exposure occurs."

DIPHTHERIA AND PERTUSSIS ANTIGENS, SIMULTANEOUS AND MIXED

Since 1938, a total of 464 Infant Welfare children were injected with the two antigens at the same time. To determine whether mixing diphtheria toxoid and pertussis vaccine might lessen or augment the antigenic value of either or of both components, two groups of children were injected. A group of 208 children were injected simultaneously with the 15,000 million per ml. vaccine (2, 2, and 3 ml.) and in the same arm with diphtheria toxoid (1, 1, and 1 ml.), at 3 week intervals. A group of 256 children were injected with the antigens mixed * (15,000 million pertussis bacilli

in diphtheria toxoid). The mixed antigens were prepared so that each dose of 2, 2, and 3 ml. equalled that when the antigens were given simultaneously. Injections were given in alternate arms at 3 week intervals as customary, just beneath the skin,[†] to retard absorption, produce maximum response, and lessen systemic (febrile) reactions. Parents were informed that the injection might be followed by a local reaction and fever of short duration. They were cautioned not to apply any local treatment. Taking the temperature was discouraged. They were instructed to give 3 or 5 grains of aspirin during the night if the child became restless or feverish. No instance of local infection occurred. Practically the only interruption in the routine administration of the injections occurred in the children who contracted intercurrent diseases. Those who failed to complete the series of injections were in families who moved away.

Schick tests,[‡] complement-fixation tests, and determination of diphtheria antitoxin concentration of the serum were performed before and after completion of the injections. The retests were performed at various intervals after completion of the injections, to compare the effectiveness of the simultaneous and mixed methods of antigen administration, and to ascertain the best time for the follow-up complement-fixation test. Schick test readings were performed 72 hours after 0.1 ml. of Schick test material was injected intracutaneously in the flexor surface of the left forearm; retests were performed on the right forearm. Diphtheria antitoxin concentration determinations were per-

* Through the cooperation of Drs. L. T. Clark and N. S. Ferry, of Parke, Davis and Company, the mixed antigens were prepared according to detailed specifications. The mixture contained 5 to 7 recently isolated, hemolytic cultures of *Hemophilus pertussis* bacilli, grown on Bordet-Gengou medium containing defibrinated human blood. The growth was scraped from the culture medium and suspended in 0.85 per cent salt solution containing Merthiolate 1:5,000. After refrigeration at 5° to 10° C. for several weeks, it was cultured for sterility and examined microscopically for absence of contaminants. Each lot was standardized to contain 30 billion *Hemophilus pertussis* per ml. An equal volume of Diphtheria Toxoid, Plain, was added to the suspension to make a final concentration of 15 billion *Hemophilus pertussis* and an equivalent of 0.5 ml.

of diphtheria toxoid in the mixed antigens. Preliminary series of mouse inoculations were conducted with increasing amounts of mixed antigen before any child was injected. Various lots of mixed antigens were used.

† Intradermal injection would produce a more severe local reaction; intramuscular injection accelerates absorption and is more likely to cause fever.

‡ The Schick test material was provided by the Illinois State Board of Health.

formed by Mr. Jones* on 82 infants before and after completion of the injection of mixed antigens. All showed less than 0.002 unit of antitoxin per ml. of serum at the preliminary test. The antitoxin concentration exceeded 0.002 unit per ml. of serum in 89 per cent of the children when retested 3 to 6 months after the final injection. The highest incidence and degree of antibody response seemed to occur when the retests were performed 6 weeks after completion of the injections. Details of the technic for the pertussis complement-fixation test have appeared in the chapter "Pertussis" in Brennemann's *Practice of Pediatrics*.

the antigens simultaneously, and 168 had the mixed antigens; 183 had only the follow-up tests. Of the latter, 84 per cent showed positive complement-fixation reactions. All but one of the negatives became positive 3 weeks after receiving a "stimulating" dose of 2 ml. of plain 15,000 million pertussis vaccine, as first used by Wu and Chu.⁶ The preliminary tests were discontinued on these 183 children because it had been found in our previous studies that practically every child had no antibodies for diphtheria as well as for pertussis before injections were given. The follow-up tests are now performed 6 weeks after completion of the injections. Any child

TABLE 1

*Preliminary and Follow-up Schick Tests and Pertussis Complement-Fixation Tests
(Antigens injected at 3 week intervals)*

Number of Children		Pertussis Complement-	
		Schick Test Per cent Positive	Fixation Test Per cent Positive
113 (Antigens Simultaneous)	Before injection	96	6
	After injection	2	91*
168 (Antigens Mixed)	Before injection	93	4
	After injection	5	73*

* All of the complement-fixation negative children (9 per cent and 27 per cent respectively) became 3+ or 4+ positive when retested 3 weeks after a "stimulating" dose (2 ml. of 15,000 million per ml.) of *Hemophilus pertussis* vaccine.

When it was found that serum antitoxin determinations coincided with the Schick test readings, blood serum titrations were discontinued, and the Schick test was used as the sole index of immunity to diphtheria. Of the 464 Infant Welfare children who had the two antigens at the same time, 281 were tested before and after the injection; 113 had

in either series whose pertussis complement-fixation follow-up test was either 1+ or 2+, was given the "stimulating" dose. Forty-four children who had shown good immunity response after injection of mixed antigens were retested 1 to 2 years later. Their Schick tests and pertussis complement-fixation tests still showed a high level of immunity; reversion had not occurred.

Table 1 is a summary of the preliminary and follow-up pertussis complement-fixation tests and Schick tests for diphtheria. The two series—simultane-

* During the early part of the study the complement-fixation tests were performed by Frank G. Jones of The Lilly Research Laboratories; since May, 1940, by Eva Markley of the Whooping Cough Research Laboratory.

ous injection and mixed antigen—are compared. The pertussis antibody response in both series compared quite favorably with the response when months intervened between the plain pertussis vaccine injections and the diphtheria toxoid injections. The Schick test as an index of protection against diphtheria was equally good in both series. The diphtheria toxoid maintained its antigenicity when mixed with the pertussis vaccine. Synergistic action was not observed.

It is too soon for an adequate evaluation of clinical results. In several minor outbreaks of pertussis among noninjected Evanston children, a few of the injected children of both series were intimately exposed, but no injected child was known to have developed pertussis. From the above data it appears that older infants and young children can be protected against both pertussis and diphtheria by the administration of 3 doses of the mixed antigens at 3 week intervals. The number of injections for protection against these two diseases is thus cut in half.

SUMMARY

1. In 3 years, a total of 464 Infant Welfare children, 8 to 24 months of age, were injected against whooping cough and diphtheria at the

same time. In 208 of the children, the two antigens, pertussis vaccine (15,000 million bacilli per ml.) and diphtheria toxoid were injected simultaneously. In 256 children the two antigens were mixed.

2. Schick tests, and pertussis complement-fixation tests were performed before and after administration of the antigens in 113 children injected simultaneously and in 168 children injected with the mixed antigens.

CONCLUSION

Immunization responses (Schick tests and pertussis complement-fixation tests) after 3 doses of mixed antigens at 3 week intervals compared favorably with those obtained after separate injections of equivalent amounts of the antigens. This experience with mixed pertussis and diphtheria antigens should warrant further trial on a large scale in the immunization programs of health departments and private physicians.

Influence of Wetting Agents on Various Antiseptics*

C. VIRGINIA FISHER, PH.D.

Warner Institute for Therapeutic Research, New York, N. Y.

IN the past few years, surface tension reducing agents, or so-called "wetting agents," have been put to use in various industries. They are being extensively used in the tanning, textile, paper, metal processing, paint, laundry, insecticide, lubricating, cosmetic, and rubber industries, etc. More recently the bacteriostatic and bactericidal effects of wetting agents alone and in conjunction with standard antiseptics have been investigated.

Scales and Kemp¹ demonstrated that synthetic organic detergents could be used for some sterilizing procedures in place of chlorine. They pointed out that wetting agents spread much more easily over a greasy surface and had the advantage of being noncorrosive to metals. Petroff and Schain² recommended the use of a wetting agent (Tergitol O8) as an aid in the digestion and concentration of tuberculous pathological material. The cleansing and sterilizing of ureteral catheters with a 12½ per cent solution of Tergitol O8 was suggested by Winer and LaCava.³ They found that such a solution was powerful enough to kill the tubercle bacillus.

Miller and Baker⁴ and Baker, Harrison, and Miller⁵ studied the action of numerous synthetic detergents on the metabolism of bacteria by the manometric method. They concluded that all the cationic detergents studied were very effective inhibitors of bacterial metabo-

ism. Gram-positive and Gram-negative microorganisms were equally sensitive to the action of cationic detergents, but the anionic detergents selectively inhibited the metabolism of Gram-positive organisms only. Cationic detergents exhibited their maximum activity in the alkaline pH range and anionic in the acid range. Certain detergents were found to stimulate bacterial metabolism at concentrations lower than the inhibiting values.

Scales and Kemp's⁶ results indicated that anionic detergents in solutions acidified to a pH of 4.0 were equally active against Gram-positive and Gram-negative organisms and that the germicidal properties of all wetting agents they studied were more pronounced when the pH values were in the lower acid range. They recommended the use of certain wetting agents in this category for the sterilization of milk cans, drinking glasses, and other utensils in public establishments.

Petroff and Schain⁷ carried out phenol coefficient tests with a long list of wetting agents alone, and in conjunction with standard antiseptics such as phenol, chloramine T, azochloramid and merthiolate, among others, and found that these antiseptics killed in much higher dilutions when combined with dilutions of wetting agents as high as 1:5,000 and 1:10,000. In the treatment of empyemas they used dilutions of azochloramid 1:3,300 mixed with tergitol 1:2,000 for irrigations and found the results encouraging in the treatment of mixed

infections of staphylococcus, streptococcus, and pyocyanus. Kintz⁸ has employed azochloramid in combination with sodium tetradecyl sulfate and sulfanilamide, combined with the same wetting agent in the treatment of infected wounds of the soft tissues of the face, obtaining better results and speedier recoveries than he obtained

with other solutions which he investigated.

Ordal, Wilson, and Borg⁹ investigated the effect of several types of soaps alone and in combination with wetting agent sodium lauryl sulfonate on the germicidal action of phenolic compounds. Their work was done in moderately alkaline solutions where the pH of the

solution was rigidly controlled. They concluded that the addition of the wetting agent in general increased the germicidal activity of such phenolic solutions.

Gershenfeld and Witlin¹⁰ have reported that the addition of 39 available marketable surface tension reducing chemicals commonly employed as wetting agents in concentrations of 0.1 per cent, 0.5 per cent, and 1.0 per cent respectively did not increase the bactericidal or bacteriostatic efficiencies of 16 phenolic, 10 mercurial, and 2 halogen compounds when no adjustments to specific hydrogen ion concentrations were made. On the other hand, when Gershenfeld and Perlstein¹¹ adjusted the pH of phenol, mercury bichloride, merthiolate, and hexylresorcinol to a pH

of 4.0 with the addition of a wetting agent, marked increases in bactericidal activity were obtained.

Gershenfeld and Milanick,¹² studying the bactericidal action of surface tension depressants alone, reached conclusions regarding the effect of pH similar to those expressed by Baker, Harrison, and Miller.⁵

EXPERIMENTAL PROCEDURES

The reports discussed above have used varied methods for demonstrating bactericidal effects of wetting agents. The purpose of this investigation was to study their effects by a standard procedure such as the phenol coefficient method. All experiments were carried out as described in *Circular 198* of the Food and Drug Administration. The

wetting agents studied are shown in Table 1. Tables 2 and 3 show the killing action of the wetting agents alone, as well as the effect of pH change. All pH adjustments were made with 0.1 normal HCl or 0.1 normal NaOH, values being determined with the Beckman pH meter. After adjustments of the wetting agent to the desired pH, further dilutions were made with water adjusted to the same pH.

Since Nacconol FSNO gave slightly better results than the other anionic wetting agents, it was chosen to represent the anionic detergents. Preliminary experiments with Nacconol had indicated that it caused very little change in

the pH of antiseptics to which it was added, whereas Tergitol O8 and Duponol WA did. Triton NE Concentrate was chosen since it was then the only neutral wetting agent available. Triton K-60 was studied further instead of Triton K-12; although the latter gave the better bactericidal results, discontinuance of commercial manufacture made Triton K-12, unavailable for continued study.

Phenol coefficients for *Staphylococcus aureus* at 37° C., obtained with and without the addition of wetting agents, are shown in Table 4. Those obtained for *Eberthella typhosa* at 20° C. are shown in Table 5.

DISCUSSION

Although the testing of antiseptics by the phenol coefficient method is not an ideal procedure, it nevertheless serves as a standard by which bactericidal activity may be compared. We found, as has been pointed out by several investigators,^{1, 5} that cationic detergents as exemplified by Triton K-60 are more active bactericidal agents than anionic wetting agents. No previous work with a neutral wetting agent such as Triton NE has come to our attention. From the standpoint of compatibility with standard antiseptics, the anionic detergents as represented by Nacconol, were found to be more generally useful.

While pH plays a definite rôle in activity of antiseptics, as has been shown by many workers, adjustment of pH is often difficult, impossible, or impractical. The choice of a wetting agent

to be added to any given antiseptic should be determined on the basis of practicability and compatibility. In our experience no single wetting agent could be depended upon to enhance the bactericidal activity of all types of antiseptics.

The ideal antiseptic is still to be found, but it is believed that these surface tension depressants offer great possibilities for increasing the activity of existing bactericidal agents.

CONCLUSIONS

1. The addition in dilutions of 1:1,000 of surface tension reducing substances, whether cationic, anionic, or neutral, enhance the bactericidal activity of mercury bichloride, mercury oxycyanide, chloramine T, argyrol, and potassium permanganate.

2. Little or no increase in bactericidal activity was noted when these same substances were added to phenol, cresol, or tincture of iodine.

3. No single wetting agent was equally effective in increasing bactericidal activity of mercurials, halogens, phenolic, silver protein, and oxidizing compounds.

4. Compatibility of the wetting agent and the antiseptic is an important consideration.

Conservation of Man Power

A 3 DAY conference on the conservation of man power in war industries will be held in Washington, April 9-11, under the auspices of the U. S. Public Health Service.

Governmental industrial hygienists from the National Institute of Health and 36 states will meet in joint session with the Subcommittee on Industrial Health and Medicine of the Health and Medical Committee, Office of Defense Health and Welfare Services.

"The health problems of a vastly increased labor force in the war industries demand the best efforts of government, management, labor, and medicine, in order to conserve the energy and efficiency of every worker," Dr. Parran said in announcing the conference.

Even in normal times, 400,000,000 man-days are lost annually in industry because of sickness and accidents. A large part of this wastage can be pre-

vented. Representatives of the medical profession, governmental industrial hygiene services, management, and labor will participate in the discussion of ways and means to reduce industrial disability.

Federal Security Administrator Paul V. McNutt, Channing R. Dooley, Director of the Training within Industry Branch, War Production Board; Dr. Clarence V. Selby, Medical Director of the General Motors Corporation; Dr. Orlen B. Johnson of the American Medical Association's Council on Industrial Medicine; and Dr. James G. Townsend, Chief of the Division of Industrial Hygiene, National Institute of Health, will be among the principal speakers.

The conference, which will be opened by Surgeon General Parran, will meet in the auditorium of the Social Security Building, 4th and Independence Avenue, S. W.

Workers' Health Education*

ELIZABETH G. PRITCHARD

*Associate Health Education Specialist, U. S. Public Health Service,
Washington, D. C.*

A SPRAY-painter in his middle 40's recently expounded during an entire lunch period on his hobby—stamp collecting. He was quite at home in the shop talk of the ardent philatelist. His own collection had been shown at an exhibition of rare items from the conquered nations. He said he had begun to collect stamps in grade school. An interested librarian selected books for him. He kept at it until he "knew all the ropes" about selecting and mounting stamps. Later he joined a club and "got wise" about trading and building a collection.

That day, a safety engineer was making an air determination at this man's station where a toxic fume exposure was suspected. When asked what the engineer was doing, the worker replied—with as much conviction as he discussed philately—"You see, lady, we need plenty of salt to keep healthy. He is trying to find out if there is enough salt in the air. If there isn't we can take salt tablets."

This worker's 35 years of experience in stamp collecting will not save him or his employer one hour of time lost because of sickness. Given a similar background of knowledge and skill in ways to protect his health, he and thousands like him can make a significant contribution to the reduction of disability in industry.

All of us need much information and

practice before we become proficient in our management of any department of living. So the worker needs instruction in health matters, and he needs the opportunity to practise what he knows if he is to manage his health problems with good judgment. This indeed is the objective of workers' health education—to provide information and experiences which make for better health and better coöperation with the industrial hygiene program. Without the worker's coöperation, it seems clear that efforts on the part of industry and public health workers will not function to the maximum benefit. The slowness with which instruction of workers has developed as an industrial hygiene activity is only part and parcel with the general lag in health education for adults.

The aging of the population in the United States has increased the public importance of young adults and older people. It has brought about fundamental changes in education. It has played a little recognized part in the creation of a surplus labor supply. It has focused public health attention on the chronic degenerative diseases. Nevertheless, the major share of health education effort is still directed toward the protection of infants and children under high school age. Health education of adults by responsible agencies has been directed principally to informing them about community sanitation, a few specific diseases (tuberculosis, venereal diseases and cancer), maternal care, and parents' responsibility for children's

* Read before the Industrial Hygiene Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

health. There has been very little effort to help adults deal effectively with situations directly affecting their personal health.

I need only mention here that these general problems of adult health are the principal causes of absenteeism, loss of income, and premature dependency among industrial workers. In addition, workers have the special problems incident to their occupations.

Labor and industry, public health workers and educators have all been slow to recognize the necessity for incorporating workers' health education into their programs. A few large employers have blazed the trail by integrating educational activities with their medical services. Insurance companies too have pioneered in the provision of educational materials. But we may look in vain to the literature of labor and public health for more than passing reference to the need for health instruction of workers. When we recall that not more than one-seventh of the workers are employed in industries providing full-time medical services, the opportunity of the industrial population to secure health education seems very limited.

In the meantime, advertisers have fully exploited the adult's need for health information. Reading a "patent medicine" advertisement and taking a worthless nostrum are assuredly not the instruction and experience we want in workers' health education. But it is "education" in the sense of learning and doing. And this will be the kind of health education workers get unless something better is offered.

HEALTH EDUCATION MATERIALS

This year, the U. S. Public Health Service decided to enter the field by making available educational materials for use in workers' health education activities. The provision of materials is only a part of the large job that waits

to be done. But, as in any educational program, the first requirement is for adequate tools in the various media of mass communication.

The program has been developed by the Division of Industrial Hygiene and the Division of Sanitary Reports and Statistics. The production schedule includes some twenty illustrated leaflets, a series of color posters, photographic exhibits, electrically transcribed radio programs, and a motion picture. The leaflet series was planned several months in advance of the posters and the radio program, hence production of the printed materials is much further along. To date, 4 leaflets have been released by the Government Printing Office, and we are momentarily expecting delivery of a fifth.

It was planned to cover in the leaflet series ten important non-industrial health problems and ten situations directly related to the job. The first group—the general health group—includes: influenza, appendicitis, stomach disorders, pneumonia, arthritis and rheumatism, nutrition, the health of women workers, mental health, heart disease, and kidney disease. The occupational group includes: carbon monoxide, benzol, the preemployment medical examination, dermatoses, changes in temperature and high humidity, infection of minor wounds, dust diseases, good housekeeping on the job, lead poisoning, and hydrogen sulfide.

The selection of these topics may be of interest. It offers an example of coöperation between two divisions of a health agency in the development of educational activities. Since time and funds were limited, it was necessary to select for first attention subjects that (a) affect large numbers of workers in the majority of industries, and (b) have not already been adequately covered in the existing health education literature.

The Division of Industrial Hygiene had precise information on the principal

causes of non-industrial sickness. Recent surveys also indicated the numbers of workers employed in occupations potentially hazardous. The work of the division in the promotion of industrial hygiene services further gave information on particular needs of the field.

The Division of Sanitary Reports and Statistics had extensive information on existing health education materials and their sources of distribution. Hence, it was possible to balance the problems needing attention against the availability of suitable materials and proceed without duplicating educational effort.

In the selection of occupational diseases and health practices on the job, we had an unlimited choice. Among 2,500 pamphlets produced by 115 agencies, only 36 publications on industrial hygiene were found. At best, only 20 of these were written to inform the worker on potential hazards and the means to avoid them.

The excellent educational materials of the National Safety Council covered only first aid procedures and personal hygiene. Moreover, distribution of these materials to workers was dependent upon their purchase by employers.

The Bureau of Labor Standards, U. S. Department of Labor, had produced a series of leaflets presenting the cause, symptoms, and methods of prevention of certain industrial poisons. These publications are not illustrated, nor have they much to command interest on the part of the individual worker. As in most health education materials there is little in the series to explain the "why" of the procedures recommended or the relation between cause and effect.

There appears to be some apprehension in certain industrial quarters lest information on occupational diseases "scare the workers" into quitting their jobs or claiming compensation for imagined sickness. Time does not permit debating this point, but I should like to state the position of the Public

Health Service. In many cases, medical and engineering control of hazardous exposures depends heavily upon the alertness of the worker and his compliance with regulations. It is too late to develop this awareness and coöperation *after* an exposure produces cases. Information should be looked upon as a *preventive* measure.

In the preparation of our leaflets on occupational exposures, we have taken the preventive approach. Every effort has been made to present the positive side of the story, at the same time warning against the potential consequences of the hazard.

Our guide in preparing the Workers' Health Series has been the requirements laid down by James Harvey Robinson 15 years ago in his book *The Humanizing of Knowledge*. He holds that writing for the general reader must do three things: (1) enlist the reader's attention; (2) present the facts and information in terms and in an order that will be understood by him and will fit into his way of looking at things; and (3) it should wisely suggest the significance of the information in relation to the reader's thought and behavior, and in his relationships with others.

The non-industrial subjects to be covered in the Workers' Health Series have been mentioned. Let us now turn to the existing health education materials and see whether these subjects have been adequately covered and are generally available to our rapidly growing employed population.

Influenza and pneumonia stand high on the list of disabling illnesses among industrial workers. In the group of 2,500 pamphlets previously mentioned, only 6 were devoted to influenza. These were produced by state departments of health, and hence their availability was limited. Moreover, the publications were virtually useless for workers' education since they dealt with public health control measures or were reprints of

statements which had been issued 23 years ago.

The 7 pamphlets on pneumonia which had been prepared for the general public were produced by five state health departments and two insurance companies. However, all of these had been published before the introduction of the sulfonamide drugs.

Stomach disorders, exclusive of cancer, are the second most frequent cause of disability among workers. In the entire group of 2,500 health pamphlets there was not one on this subject. The same is true of the health problems of women workers. Gafafer reports the rate of disabling sickness of females as 63 per cent in excess of that among males. The only significant educational materials for women found in our pamphlet collection were on maternal care. In this field, official health agencies and private organizations alike have done an excellent job. There were one or two items on "reducing" and "posture." But there was nothing designed to shake the curious apathy of women to constructive attention to their health. The extensive advertising of remedies for the "relief" of menstrual disorders and of other diseases which score high disability and death rates among women suggests that this is a fertile field for sound health education.

Every responsible group has put off facing the difficulty of teaching adults about their mental health problems. But face it now we must. Industry and medicine know that mental disorders cripple production. This is so whether the disorder be frankly psychotic or mild or even buried beneath physical ailments or problems in personnel management.

Virtually all of mental hygiene educational effort to date has been directed toward the behavior of children. For example, only 22 pamphlets in 2,500 were on mental hygiene; of these, 2 were on mental problems of old age. Only

one attempted to cover the general subject of mental disease and the causative factors. It is clear that educational materials on mental problems for industrial workers will be difficult to prepare. We shall be breaking ground, and shall need a great deal of help. Anything prepared at this time will have to be regarded as an experiment. One of the pamphlets in our collection suggests a fruitful line of approach. This is *Making the Most of Maturity*, publication Company. No attempt has been made to teach mental hygiene concepts as such; but through stimulating aging people to take up a hobby, practical application of mental hygiene concepts to daily life are made in such ways as to arouse the interest of the reader and help him relate the information to his own living. It may be that through such an indirect approach we can gradually make a dent in popular resistance to any reference to mental disease and psychiatry.

And so it goes—nutrition, arthritis and rheumatism, heart diseases, appendicitis, kidney diseases. Few, if any, educational materials suited to the abilities and interests of the average adult. How to avoid sickness and how to meet it if it strikes, how to live well and happily—these are serious questions for the millions who come out of elementary school and high school and go to work with little knowledge or skill in health protection. Their usual informational background is advertising copy plus the fatuous theory that if you obey the rules of personal hygiene and live rightly, you will come unscathed to a ripe old age and die with your boots on.

In workers' health education—which is adult health education—we must build a new background, not only to promote health but also to make sure that when sickness strikes, the individual will reach for a doctor and not for a bottle of little pills.

DISTRIBUTION OF EDUCATIONAL MATERIALS

The provision of materials is of no account unless they are placed in the hands of the individuals for whom they were prepared. The Public Health Service has developed the workers' health education program as a part of its cooperative industrial hygiene activity with states and industries. Hence, ultimate responsibility for placing the materials in the hands of workers lies outside the federal agency.

Fifty thousand copies of each leaflet are purchased by the Public Health Service from the Government Printing Office. This purchase includes the initial cost of production. Our distribution plan is to send 1,000 copies to each state and local industrial hygiene unit free of charge. At the present time, the number of such units absorbs 41,000 of our free copies. In addition, 100 copies are sent to state departments of health having no organized industrial hygiene service. Sample copies are sent to a list of interested organizations, including industries, other federal departments, labor unions, and voluntary health agencies.

An effective distribution program has not yet been developed. One state distributed all of its copies to the labor unions, and thus missed the opportunity of securing substantial distribution through many interested plants. Another state distributed its copies to industry only, and thus missed recruiting the support of labor and the value of distribution through the auxiliaries and welfare services of unions.

Vermont, with a relatively small working population, has devised an interesting way of providing health information to workers and of stimulating educational activity. With the cooperation of industry and labor, "health clubs" are being formed by the workers in many plants. The State Department of Health provides each worker who joins a club

with a membership card and button, and also agrees to supply educational materials on any subjects interesting the individual member or the group. Thus, there is an opportunity not only to "sell" industrial hygiene but other public health activities.

Sample copies of the posters now in production will be circulated, and the motion picture and the electrically transcribed radio dramas will be available for loan without charge (except transportation) to interested groups.

The workers' education program of the Canadian Department of Pensions and National Health got started a little in advance of the Public Health Service program. The Canadian Division of Industrial Hygiene is distributing leaflets and posters on occupational diseases. They have not yet attacked non-industrial disability. The leaflets are very similar to the ones produced by the Bureau of Labor Standards; they have the usual drabness of governmental publications, and use technical terms freely with the result that the material, on the whole, is more difficult for the worker to read and interpret than our American leaflets.

Nevertheless, the Canadian program has reached the majority of Canadian workers through a well planned distribution program. The materials are distributed free of cost to all. Immediately upon publication, one or two copies are sent to all industries in the Dominion where the material—benzol, TNT, etc.—discussed in the leaflet is used in manufacture. A form letter inviting the plants to order additional free supplies for distribution to each of their employees accompanies the leaflet. Dr. Kingsley Kay, who has been responsible for the program, reports that this method has met with only a moderate response, even though the materials were free.

Greater success was obtained by publicizing the educational program. The

leaflets were announced in the newspapers, trade magazines, and professional journals. The trade journals and newspapers eagerly accepted the information and urged workers to write for copies. As a result, thousands of requests were received from individual workers. These requests were supplied directly by the Division of Industrial Hygiene.

It is the policy of the Public Health Service to encourage individuals to seek information from their state or local services. Hence, no effort is made to stimulate individual requests to the Service. However, state and local industrial hygiene services may find some of the Canadian methods useful.

The cost of production and the number of workers to be reached are so much greater in the United States than in Canada that no one agency can be expected to bear the total cost of distribution. The Government Printing Office, therefore, offers for sale at quantity prices large supplies of the Workers' Health Series at the time the free supply is released.

To date, 153,043 of the first three Workers' Health Series leaflets have been sold by the Government Printing Office. The most popular of the first three has been *Leonard's Appendix and How It Burst*. Our free supply has been exhausted for some months and 69,774 copies have been sold. The leaflet on carbon monoxide, *KO by CO gas*, was released in July and 47,300 copies have already been sold. The first in the series, *But flu is tougher*, has sold fewer, 35,923 copies, but this is believed to be largely due to the fact that the "flu" season was almost over by the time the leaflet was released.

The fourth, *Clara gives Benzol the run around*, just came off the press this

week. The fifth, on stomach disorders, *Trouble in the Midriff*, is promised before the end of the month.

The channels for health education of the worker are manifold. It is hoped that all interested organizations and professional people will join with us in exploring and promoting every opportunity. Industrial hygiene services are offered so many educational opportunities in their relations with workers that it is hard to know where and how to begin. Yet we must admit that among millions of workers, opportunities are being missed. Authorities in the field have told us repeatedly how beneficial the services of the industrial physician have been in securing the coöperation and friendly response of workers. The same opportunities for health education are open to nurses in industry, engineers, chemists, and industrial hygienists. It is not possible to secure the desired response from the worker every time an educational opportunity is offered. Education in any field requires patience and insight. It requires sympathetic understanding of the people we wish to influence. There is no place for cynicism in workers' health education. To be sure, we shall repeatedly meet with discouragement; we shall meet, in many cases, provoking resistance to our efforts, but we must remember that much of our difficulty may be chalked up to past neglect.

Our country is founded on faith in the integrity of the individual, in his ability to learn through the free communication of ideas. This belief has not failed us in the past. It will not fail us in our efforts to improve the health of workers if we accept the challenge along with the promise of thereby being able to render fuller and more effective service.

Use and Abuse of *Staphylococcus aureus* as a Test Organism*

CHARLES M. BREWER, PH.D., F.A.P.H.A.

Insecticide Division, Agricultural Marketing Service, U. S. Department of Agriculture, Beltsville, Md.

THE use of *Staphylococcus aureus* as a test organism dates from the earliest history of germicidal testing, when Koch, Fischer, and Esmarch dried this organism on silk threads and Sternberg initiated the drop method of test. It is the most generally utilized micro-organism for antiseptic tests, and at present the only one with a standardized resistance suitable for this purpose. Apparently use by the U. S. Department of Agriculture of *Staphylococcus aureus* as an organism, for regulatory work in testing antiseptics and disinfectants not only stimulated general activity in the field of antiseptic testing, but too frequently, and quite unfortunately, led to the conclusion that the procedures described in *Circular 198*¹ are the only methods necessary for gauging the value of antiseptic substances. This is certainly far from the actual case. Used in these routine methods for comparing antiseptics and as a means of obtaining standardized measurements of relative germicidal or inhibitory qualities of products under certain conditions, *Staphylococcus aureus* of the prescribed resistance has proved itself very useful. However, no single standardized test is sufficient for ascertaining the merits possessed by a substance when used as an antiseptic under practical conditions of use. It was not anticipated that the laboratory tests set forth in *Circular 198*

would be utilized as the sole criterion of antiseptic efficacy. As a matter of fact, such tests are of value in demonstrating the worthlessness of a preparation, but fail to inform us of the effectiveness of an antiseptic under the modified conditions of use on or in the human body.

Although a strain of *Staphylococcus aureus* employed for testing purposes may be shown to possess definite resistance to germicidal action, such a fact conveys but little information concerning its value as a test organism for measuring the inhibitory or growth-preventing properties of a substance. Marshall² has stated that germicidal and inhibitory action differ only in degree. From a practical point of view the two qualities are quite distinct. The capacity to resist exposure to destructive agents for only short periods of time and the ability to proliferate under continuous adverse conditions are separate characteristics.

In spite of its well recognized resistance to germicidal agents, *Staphylococcus aureus* is well known as being more fastidious in its growth requirements than many other organisms of common occurrence. Consequently, its multiplication on laboratory media is more easily inhibited. In making tests with the agar plate or agar cup plate method, many substances at concentrations which have no effect upon the growth of an organism, such as *Escherichia coli*, produce definite zones of inhibition when *Staphylococcus aureus* is employed as the test

* Read before the Laboratory Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

organism. Indeed, because of the sensitivity of *Staphylococcus aureus* to mercury and silver, this organism with the agar plate technic can be utilized to detect minute concentrations of such heavy metals when combination with other materials makes their detection by chemical means very difficult. To credit inhibitory antiseptic value to preparations, or to ascribe value to so-called antiseptic flooring or sanitized materials, as has been done, on the basis of tests performed with *Staphylococcus aureus* as the only test organism, is unwarranted.

Although *Staphylococcus aureus* is relatively resistant among vegetative microorganisms, preparations found to be capable of killing it by the F. D. A. methods actually have not been subjected to exacting tests, nor have they demonstrated their capacity to kill organisms likely to be encountered under the various practical conditions of use. In utilizing the phagocytic ability of leucocytes against artificially opsonized cells of *Staphylococcus aureus* of standard resistance to determine the relative toxicity of antiseptic substances, Welch³ used whole blood as a constituent of the test. In determining toxicity indices, based upon toxicity compared with germicidal effectiveness under similar conditions, he found that concentrations of many products capable of killing *Staphylococcus aureus* in 5 minutes by the F. D. A. method were not germicidal in the presence of the prescribed amount of blood in 30 minutes. Consequently blood diluted with 3 parts physiological saline is now employed in that portion of the test which measures relative germicidal activity.

It has been accepted throughout the disinfectant industry that products intended for general disinfection should be recommended at dilutions equivalent to 20 times their phenol coefficient, i.e., at dilutions 5 times more concentrated than the dilution found necessary to

kill *Eberthella typhosa* of standardized resistance in 10 minutes. This practice is based not only on the fact that *Eberthella typhosa* lacks a high resistance, but also upon the recognition that those organisms which are the object of disinfection under practical conditions may be more difficult to kill than those grown in the laboratory. No such "margin of safety" is employed for assuring germicidal action in the case of recommended dilutions of antiseptics. To be sure, so inflexible and arbitrary a means of assuring positive results is hardly feasible in the case of antiseptics, where toxicity and the nature of the sites of possible application must be considered. However, it would appear that tests utilizing body fluids such as saliva, sera, and blood should certainly be employed in determining the efficiency of the recommended dilutions before antiseptics are offered for general use.

Another field in which the use of *Staphylococcus aureus* of standardized resistance is abused is in its utilization for evaluating germicidal efficiency of those preparations recommended for the disinfection, in contrast to the sterilization of instruments, including surgical, veterinary, and dental appliances. Here again the concentrations recommended for use are ordinarily based upon the ability to kill the test organism without the provisions of a "margin of safety." Such a practice is essentially fallacious and fraught with hazard in its possible consequences. The sole purpose of testing such preparations should be an assured determination of their ability to kill all vegetative microorganisms. This cannot be done with cultures of *Staphylococcus aureus* conforming to present accepted standards of resistance. The present standard of resistance rests upon an empirical and arbitrarily selected basis and is far from the highest resistance which *Staphylococcus aureus* may possess.

Between 1918 and 1922 Shippen⁴

found that several strains of *Staphylococcus aureus*, when grown in media used for culturing *Eberthella typhosa* for phenol coefficient determinations, withstood the germicidal action of a 1:60 solution of phenol for 5 minutes. Reddish⁵ later established that a number of other strains possessed this same resistance. Gradually this resistance became accepted as standard for *Staphylococcus aureus* cultured and tested according to the prescribed conditions and has persisted to the present. This resistance quite generally exceeds that of other organisms grown under similar conditions but it is inferior to that shown by *Staphylococcus aureus* grown under conditions which are only slightly different.

The strain of *Staphylococcus aureus* designated as 209 has been in use for germicidal testing since 1922 and has been widely distributed for that purpose. In our own laboratory this organism usually meets the specified resistance when cultured according to the directions set forth in the U. S. Department of Agriculture *Circular 198*, which provide for culturing for 24 hours from a 4 mm. loopful of inoculum of a broth culture in 10 ml. of medium contained in a 20 by 150 mm. test tube. The medium consists of 0.5 per cent beef extract, 1.0 per cent peptone (Armour's for disinfectant testing), and 0.5 per cent sodium chloride, in water, adjusted to pH 6.8. We have found that the resistance of this organism can be increased by decreasing the amount of beef extract, by increasing the time of the culture period, and by increasing the diameter of the vessel in which the organism is cultured, that is by increasing the surface ratio of the medium. Our studies show that there is a relationship between the amount of beef extract and the resistance of the test organism. Between the concentrations of 1.0 and 0.1 per cent of beef extract the average survival time of a 24 hour

broth culture increases from about 3½ minutes to approximately 7 minutes in a 1:60 dilution of phenol at 20° C. If the resistance of cultures of *Staphylococcus aureus* grown in 1.0, 0.5, 0.3, and 0.1 per cent beef extract broth is graphically represented by plotting resistance against concentration of beef extract a straight line results, the lower concentrations of the extract producing the more resistant cultures. With no beef extract in the culture medium, the average resistance of a number of cultures is less than that of those grown in a medium containing 0.1 per cent beef extract; however, some of these in broth containing only peptone will survive longer than any grown in broth containing beef extract. This anomaly is apparently due to the less favorable start afforded small inocula in the absence of beef extract, especially in old or well aerated media, where growth after 24 hours has reached a less advanced stage. It might be pointed out that increasing amounts of beef extract increase the population of the culture.

The increase in resistance obtained by incubating longer than 24 hours is unequal for cultures grown in different media. The resistance of cultures grown in peptone media containing 1.0 per cent beef extract will increase little if at all in 3 to 4 days' incubation at 37° C., while those grown in media containing peptone only, resist 1:60 phenol 3 times longer after a 3 day incubation period than after a 24 hour incubation period.

By using containers of a diameter larger than the 20 mm. tubes suggested in *Circular 198* for carrying the usual 10 ml. volume of medium, an increase in resistance can be obtained for cultures grown in various types of media used. Conversely, if tubes of only 15 mm. diameter are employed for carrying this amount of medium, even those cultures in broth containing an optimal amount of beef extract are likely to fail to attain the standard resistance. At the

same time it must be considered that small inocula in broth containing no extract are increasingly liable to a tardy initiation of growth in large containers. We have found that thiamin chloride in approximately 0.5 to 1.0 gamma per ml. amounts is helpful in initiating growth in such circumstances with a consequent increase in the resistance of the culture. Cultures grown under such conditions retain their superior resistance throughout the cultivation period. In culturing the organism in 150 or 200 ml. Erlenmeyer flasks where 10 ml. of broth forms a relatively thin and well aerated layer, it is advantageous to use a preliminary culture period of 6 to 8 hours in the test tube before transferring the inoculated medium to the flask.

With the modifications noted above which tend to increase resistance, we have very frequently produced cultures of *Staphylococcus aureus* surviving a 1:60 dilution of phenol, i.e., a 1.66 per cent solution, for 1 hour and at times for 1½ hours in contrast to the prescribed 5 minute survival period.* Cultures surviving this dilution for a period of 1 hour commonly survive a 2 per cent solution of phenol for 20 minutes.

We have encountered a number of preparations offered for the disinfection of instruments which are not capable of killing, in the recommended time periods, cultures of *Staphylococcus aureus* moderately more resistant than the standard.

It is apparent that more attention should be given to the standards of resistance for *Staphylococcus aureus* used as a test organism as well as to the interpretations based upon the results of the tests. Especially is this important in the testing of preparations for the disinfection of surgical instruments where the use of a test organism with high resistance is essential.

Again proper appraisal of an antiseptic may call for information not obtainable in the performance of a single *in vitro* test using as a test organism a single strain of one species of staphylococci. Obviously neither antiseptics nor disinfectants are used under such restricted conditions, nor are they recommended as efficacious against *Staphylococcus aureus* alone. The peculiar fitness of *Staphylococcus aureus* as a test organism for determining the germicidal power is readily conceded; and if circumstances arise to restrict the selection of test organisms to a single strain, it is also conceded that *Staphylococcus aureus* is undoubtedly best suited for the purpose. Certainly if a preparation fails utterly to destroy or inhibit the growth of *Staphylococcus aureus* under the conditions of the tests described in U. S. Department of Agriculture Circular 198, no merit whatsoever may be ascribed to that preparation. To this extent a single laboratory test utilizing *Staphylococcus aureus* may contribute all that need be known regarding such a substance.

On the other hand, there are numerous bacterial species much less readily inhibited in their growth by antiseptics than are the staphylococci, and among these organisms which more stubbornly grow in the presence of staphylococcus-inhibiting substances are species of real significance in the evaluation of the worth of an antiseptic. Consequently, if there is to be satisfactory evaluation of an antiseptic in terms of what might be expected of it under practical conditions of use, it will be necessary not only to take precautions to use a strain of *Staphylococcus aureus* of proper resistance and to follow meticulously certain prescribed manipulations, but to augment such procedures by the use of other test organisms and to adopt procedures designed to throw additional light on the value of the preparation. Accordingly, it is perhaps timely to

* Different lots of the prescribed peptone have had varied effects on the production of cultures with relatively high resistance. The lot available at present is superior for this purpose to the preceding lot.

suggest a fallacy in the belief that proof of the ability of a compound to destroy or inhibit the growth of *Staphylococcus aureus* under the conditions of one *in vitro* test suffices to appraise the efficiency of that compound. With all its merits as a test organism, *Staphylococcus aureus* cannot serve as such an elastic measure.

SUMMARY

The comparative usefulness of *Staphylococcus aureus* as a test organism in methods of testing disinfectants and antiseptics has been discussed. Its use as the sole test organism for inhibitory antiseptic action and the lack of a "margin of safety" in conjunction with

its utilization as a criterion of germicidal efficiency has been criticised.

It has been shown that *Staphylococcus aureus* may attain a significantly higher resistance than prescribed by the F. D. A. method. Means are described by which cultures resisting 1:60 phenol for over an hour at 20° C. are obtained.

A Nutrition Survey of a Small North Carolina Community^{*†}

D. F. MILAM, M.D., F.A.P.H.A.

International Health Division, Rockefeller Foundation, Chapel Hill, N. C.

DURING the last year and a half a nutrition survey has been carried out in a small rural North Carolina cotton mill community of about 400 population. This community was chosen as probably representative of many of the small communities of the state having a single industrial plant. The aim of the survey was to accumulate data on malnutrition in this region, particularly of the so-called subclinical deficiency states, which would serve as a basis for a program of nutrition improvement.

The determination of which individuals and what percentage of any community can be classed as malnourished is a very necessary but very difficult procedure. It is an old epidemiological slogan that no disease can be adequately controlled unless we know where, when, and under what conditions it is occurring. In the case of malnutrition it is not only the fully developed deficiency disease, *e.g.*, pellagra or scurvy, that must be diagnosed. In general, such marked symptoms come on only after prolonged privation and frequently with years of ill health preceding the definite disease. For purposes of control we need to know which individuals have set out

upon the road leading to deficiency disease. It is assumed that the very definite and disabling disease of known signs and symptoms is preceded during the long "incubation" period by a lesser degree of ill health, which for the large populations involved represents a great loss of national vigor and morale. Of the two kinds of malnutrition the "hollow" or starvation hunger hardly needs a laboratory to bring it to light. The problem involved is that more insidious "hidden hunger" that arises from partial deficiency of one or more of the essential food elements, and which, though a part of the "hollow hunger," can also arise in the midst of seeming abundance.

METHODS

In the North Carolina study the diagnostic procedure chosen was a composite of most of the known methods suitable for survey work that offered probability of yielding useful information on the problem in hand. Malnutrition is a complex stemming from conditions involving all of the metabolic processes of the body. No single diagnostic procedure, as simple as those for malaria, hookworm, or tuberculosis, could be expected to reveal this condition in its entirety. Rather, tests for certain phases could be introduced and these used as indices of the general status. In line with this plan four general procedures were followed in this study:

1. A thorough going physical examination designed to reveal any signs of deficiency

^{*} Read before the Epidemiology Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

[†] The studies and observations on which this paper is based were conducted with the support and under the auspices of the International Health Division of the Rockefeller Foundation in cooperation with the North Carolina State Board of Health and Duke University School of Medicine.

disease or any condition conducive to such deficiency

2. A careful clinical history with special probing for any symptoms of deficiency state and with a careful survey of food habits
3. An actual food intake survey on each individual covering a period of 7 days
4. The laboratory examination of a 25 ml. sample of blood

In the population studied here the physical examination was of only moderate helpfulness. More direction came from the medical history, particularly the section on food habits which frequently outlined the individual deficiencies subsequently confirmed by the other procedures. The 7 day diet records were carefully supervised during the week the recording was done so that inconsistencies were queried and corrected currently. When finished they were analyzed by reducing all entries to grams and, by use of food tables, were converted into the food elements. Analyses were thus done on each record to show daily intake of carbohydrate, protein, fat, calories, iron, calcium, vitamins A, B₁, C, and riboflavin.

The laboratory examinations made on the blood were for vitamin C, vitamin A, carotene, total proteins, albumin, phosphorus, phosphatase, hemoglobin, red cell count, and hematocrit. This type of examination being largely biochemical was outside the usual procedures of state public health laboratories. The methods for assaying the various vitamins are still in the formative phase. For these reasons and to have adequate supervision by trained biochemists interested in the problem, the Nutrition Laboratory was set up in the biochemical department of Duke University Medical School. As far as possible the Evelyn photoelectric colorimeter was employed in the work and was used in analyses of vitamin C, vitamin A, and carotene, hemoglobin, phosphorus, and phosphatase. Kjeldahls were done for total proteins and albumin, though in

the second year's work this has been replaced by the falling drop method.

The site chosen for the first survey was an old cotton mill community in the mideastern part of the state having a population of approximately 400 individuals, all of native American stock, most of whom worked in the mill. Their subsistence was largely from the cash income with very little gardening done. Full-time wages in this mill averaged about \$12 per week. The surrounding territory of some 50 square miles was included in the second part of the survey, and is a farming area, chiefly for cotton, corn, and tobacco, with rather low soil fertility. Altogether about 60 per cent of the individuals in the community were included in the survey; all ages and economic levels were adequately represented in the sample. In the mill village the population is entirely white; in the farming area the Negroes are approximately one-third of the population.

The seasons of surveys were spring and fall and these are divided in the tabulations. Two spring surveys are included. A small winter survey of adults only was carried out immediately following the fall survey.

RESULTS

The results of certain items studied have been arranged in tables with averages calculated for the community as a whole. In the tables presented here only these community averages are given, with percentages of the individuals found at different levels above or below this average. Table 1 gives some more detailed information for vitamin C in the mill community. With the exception of 6 cases of mild scurvy and 1 of active rickets, no actual existing deficiency disease was diagnosed by the survey. Twelve individuals had histories of pellagra in past years. Physical signs suggestive of early deficiency were indefinite, but the medical and dietetic

TABLE 1

1.0-1.4	13	5.9
1.5-1.9	3	1.4
Total	218	100.0

histories were more suggestive. The results here tabulated are entirely objective giving the nutritional status of the community as judged by the laboratory and diet survey technics. Very definite deficiencies are revealed by these two methods. Judgment as to the effect on bodily vigor and health resulting from these deficiencies is not a part of this paper.

DISCUSSION OF RESULTS

Caloric intake—The first item investigated was the adequacy of the diet as to quantity or energy value, *i.e.*, caloric content. It was surprising to find that for the portion of the community over 15 years of age the daily intake was, by the methods used, only 2,000 calories. This was only two-thirds of the generally accepted standard of 3,000 calories for men at light work, and looked like a real dietary deficiency. However, judgment was reserved until a control survey was made on a group of doctors and technicians at Duke Hospital who were presumably of good economic status and adequate nutrition. The caloric intake of this group was found to be identical with that of the mill village, *i.e.*, 2,000 calories. In this latter group part of the diets were found to be adequate in all other respects. The conclusion was drawn that data collected by this method show that in this latitude, men at light work can be adequately nourished on 2,000 calories per day. It is possible that the accepted

standards were set up for colder climates and also that modern diets are better balanced in the food essentials.

Vitamin C—The most outstanding finding of the first spring survey had to do with vitamin C. Normally the fasting blood contains 0.6 to 1.0 or 1.5 mg. ascorbic acid per 100 ml. plasma, or otherwise stated about $\frac{1}{2}$ to 1 part per 100,000. One-half this amount, 0.3-0.5 mg. per cent, is generally considered to be probably subnormal, and below 0.3 mg. per cent certainly so. Reference to Table 1 shows that in this small community, 83 per cent of the individuals were below this 0.6 mg. per cent minimum normal level, and 61 per cent were below the 0.3 mg. per cent level. More impressive still, 27 per cent of the 218 individuals showed no vitamin C at all, though only 6 cases of mild scurvy could be diagnosed in the community and all of them were in two families whose dietary excluded vitamin C rich foods. These low blood levels were confirmed by a dietary survey on about 40 per cent of the same individuals, well distributed and on a family basis. This showed an average daily intake of 23 mg. vitamin C, which is about one-half the minimum normal standard. However, over 50 individuals in the community with no detectible vitamin C in the blood showed no signs of scurvy. This puzzling fact is in line with recent investigations which show that in a healthy man, 6 months of nearly complete privation of vitamin C is necessary to produce clinical signs of scurvy.¹ It is probably a rare thing for complete vitamin C privation for extended periods to be met with in American diets. The above figures do show that for shorter periods this privation certainly does occur with complete disappearance of vitamin C from the circulating plasma. To assume that no ill effects were suffered just because the privation was not severe enough to cause scurvy would seem unjustifiable.

Another interesting fact about vitamin C blood levels in this community is that the very low level that existed in the spring of 1940 was greatly improved by the fall of the same year. This is indicated by a resurvey of 53 individuals in the fall as shown in Table 2. The

TABLE 2

*Plasma Vitamin C, Survey of Identical
Individuals
Spring and Fall, 1940*

Mg. per 100 ml. Plasma	Spring, 1940		Fall, 1940	
	Individuals	Per cent	Individuals	Per cent
None	3	5.7	1	1.9
0.1-0.2	20	37.7	9	17.0
0.3-0.5	18	33.9	10	18.9
0.6-0.9	9	17.0	22	41.5
1.0-1.5	3	5.7	11	20.7
Total	53	100.0	53	100.0
Mean	0.4±.04		0.8±.04	

average for this group rose from 0.4 mg. per 100 ml. in the spring to 0.8 mg. in

the fall, which latter is considered a normal level. The shift of individuals to higher levels can be readily seen in this table. It has been previously shown² that a very inexpensive diet containing 60 mg. vitamin C daily will raise low fasting blood levels to normal within 6 weeks' time. Subsequent investigations have shown the same result in a much shorter period. A dietetic resurvey in the fall was not made on these 53 individuals, but the rise in blood levels clearly indicates an improvement in dietary vitamin C intake must have occurred. Quite evidently nutrition improves over the summer months when gardens flourish, even though the produce must be purchased. It is the long winter of partial privation that leads to outbreaks of nutritional disease in the spring with actual scurvy probably occurring only in those who started the

TABLE 3

Plasma Vitamin C

Period	Group	Total Number Examined	Mg. Vitamin C per 100 ml. Plasma Per cent of Examinees at Given Level					
			Mean	None	0.1-0.2	0.3-0.5	0.6-0.8	0.9+
Spring, 1940	Mill Village White	218	0.3±0.02	27	34	22	8.7	8.3
Fall, 1940	Mill Village White	59	0.7±0.05	3.4	15.2	22	27.2	32.2
Fall, 1940	Rural White	130	0.9±0.03	0.8	7.5	16.9	20.8	54.0
Fall, 1940	Rural Colored	141	0.9±0.03	0	4.3	4.2	25.5	61.0
Winter, 1941	Rural White	54	0.75±0.08	5.5	26.0	26.0	9.3	33.2
Spring, 1941	Rural White	51	0.8±0.06	0	21.5	15.7	5.8	57.0
Spring, 1941	Rural Colored	75	0.6±0.04	1.3	18.7	38.6	17.4	24.0

Suggested vitamin C standards: 0.9 mg. per 100 ml. plasma and above is a normal level; 0.6-0.8 mg. is probably within normal limits; 0.3-0.5 mg. is probably subnormal; 0.2 mg. and below is definitely subnormal.

TABLE 4

Plasma Vitamin A

Period	Group	Total Number Examined	Int. Units Vitamin A per 100 ml. Plasma Per cent of Examinees at Given Level					
			Mean	0-34	35-69	70-99	100-149	150+
Spring, 1940	Mill Village White	206	32±0.8	63.5	36.5	0	0	0
Fall, 1940	Mill Village White	59	56±2.5	15.3	64.5	20.2	0	0
Fall, 1940	Rural White	128	69±1.6	0	59.5	36.0	4.5	0
Fall, 1940	Rural Colored	126	64±2.3	4.7	69.0	19.1	5.6	1.6
Winter, 1941	Rural White	47	87±3.8	0	31.9	40.4	25.6	2.1
Spring, 1941	Rural White	49	65±2.0	0	63.2	32.7	0	4.1
Spring, 1941	Rural Colored	72	55±1.5	7.0	81.9	11.1	0	0

Suggested vitamin A standards: For males the normal range is 70-170 International Units per 100 ml. plasma; for females, 100-200.

winter in a depleted state as far as this vitamin is concerned. It is the summer recovery period that prevents more serious outbreaks. Perhaps this is the cycle the race is attuned to—winter privation, summer recovery. That it makes for the best in the race is quite questionable. Modern storage methods, including pressure cooker canning and rapid freezing of fresh vegetables, has made it possible to by-pass this stone age cycle and carry over the summer abundance to reduce the scarcity of winter, not only dried and easily stored foods, but also the succulent, life sustaining vitamin C foods. The above figures indicate that a large percentage of the population of which this community is representative is quite inadequately served by these modern methods in food storage and marketing technics. This vitamin C problem is so closely tied up with several other essential food element privations that solving one will solve several problems.

In interpreting the tables showing seasonal variations it is to be stressed that with the exception of Table 2 on vitamin C, the groups shown in the tables are not identical, and comparisons from season to season are therefore not justified. It is worth mentioning that the suggested increased intake levels in the spring of 1941, especially in the Negro,

could well be due to the government distributions of surplus commodities to the schools, chiefly citrus juices and milk.

Other vitamins—Other findings in the survey can be read from the tables. Vitamin A levels in the blood plasma were at the bottom of the suggested normal band. This checks with the food intake study which showed the carotene or provitamin A content of foods eaten were just at the minimum normal level. When it is considered that probably as low as 50 per cent of this is actually converted into vitamin A in the body, then the inadequacy of intake becomes evident. A borderline adequacy is an unsatisfactory level; any accident, sickness or fever would greatly increase the need and throw the individual promptly into a deficiency state.

Vitamin B₁ (thiamin) intake of about 700 micrograms daily as found in the first spring survey was only about one-half the minimum normal standard. In the Negro population the intake was below one-third the normal level. This fits in well with the clinical finding that a large percentage of hospital patients respond well to vitamin B₁ concentrates. For the non-hospital population a procedure far more rational than the propaganda for generalized use of vitamin concentrates would be the encourage-

ment of the use of vitamin B₁ rich foods in the diet, particularly whole cereals and whole grain breads which rank as cheap foods. By this method other necessary food elements, even some unknown ones, would be included.

Riboflavin, a member of the B complex, is now more generally recognized as a vitamin, privation of which leads to a definite disease complex. It is concerned with eye as well as skin health, and is suspected of being concerned with preventing premature old age. The best and most easily available source is milk. In the mill community survey the riboflavin intake was about one-half the normal standard recommended by the Committee on Nutrition and Foods of the National Research Council; the rural white had a level somewhat higher, while the rural Negro received only about one-third the standard. The very numerous individuals who had adequate intake of this vitamin were almost invariably heavy milk drinkers. The family cow was the custom in the white rural farm family, but a rarity with the Negro.

Minerals—Closely connected with the milk intake is the calcium content of the diet. Growing children in particular stand in need of this bone-building element. The normal intake of calcium per day was fixed by the National Research Council Committee at 0.8 gm. daily for adults and 1.0–1.4 gm. for children. In the mill community survey the adults received a daily average of 0.5 gm. and the children 0.6 gm. Surveys in other groups in other seasons were slightly higher (0.77 gm. maximum) except in the Negro fall group which had 0.37 gm. average daily intake. In the spring the average Negro intake was 0.66 gm., due, it is believed, to the canned milk distribution in schools that winter by the Surplus Commodity Corporation.

The iron intake for the adult of the mill community averaged 8.9 mg. in

the spring. In the fall the rural whites had this same intake, but the Negroes had 5.7 mg. A fairly well to do rural white group in the winter had 10.7 mg. daily intake of iron, and a Negro group 7.5 mg. The former normal standard for adults was fixed at 15 mg. daily intake, but this was lowered by the National Research Council Committee to 12 mg. By such standards the iron intake in this community was definitely subnormal. It is of interest to compare this with the hemoglobin readings. In the spring, 1940, survey the mill group male averaged 13.7 gm. hemoglobin per 100 ml. blood, the female 12.6 gm.; male children under 12 years averaged 12.3 gm., female children 12.6 gm. This community was outside the hookworm and malaria areas of the state. It seems to follow from these figures that the community was only slightly anemic, with an iron intake only three-fourths the recommended level.

SUMMARY

The nutritional status of a small North Carolina mill community was surveyed in the spring and fall, 1940–1941, with special reference to the amount of preclinical food deficiency present. The methods used were clinical, laboratory, and dietetic. Results show a surprisingly low vitamin C level in the blood in the spring, but with very little scurvy present. In the fall this level in a sample of the same group was much higher and within normal limits. With the exception of 6 cases of mild scurvy and one of acute rickets, no clinical deficiency disease was diagnosed in the community.

Subnormal intake was also noted for vitamins A, B₁ and riboflavin, calcium, and iron. Blood levels were slightly subnormal in vitamin A and hemoglobin.

The community was in general considered to be moderately malnourished and in this probably representative of quite large similar groups in the state.

A program of nutritional improvement is suggested, through health education in food habits, better distribution of gardens, farm animals, and food preservation processes, and coöperation with federal surplus commodity programs.

Delayed Birth Registration

WITHIN recent months, a number of bills have been introduced into Congress, intended to permit the issuance of delayed birth registration certificates by federal agencies. The outstanding bills are:

H.R. 6600 (introduced by Congressman Dickstein). This provides for issuance of certificates of citizenship by the Commissioner of Immigration, of the Department of Justice, on the basis of "satisfactory proof." The bill also provides for the determination of age by the U. S. Department of Justice when necessary to be determined by any branch of the United States Government. This bill has passed the House and was referred on March 20 to the Committee on Immigration of the U. S. Senate.

S. 2299 was introduced by Senator Reynolds on February 23 and is at present in the hands of the Senate Committee on Military Affairs. The bill is supported by the U. S. Army and pro-

vides for a "certified birth record" to be issued by the Director of the Census upon the basis of finger prints and evidentiary records transmitted to him through postmasters of first and second class.

The Conference of State and Provincial Health Authorities of North America on March 24 voted not to endorse either bill, and instructed a committee to draw up a bill looking toward more adequate financial support and implementation of existing state systems.

Pursuant to the resolutions adopted at the Atlantic City meeting of the American Association of Registration Executives, a Commission on Vital Records has been appointed by Administrator Paul V. McNutt of the Federal Security Administration to study the problems of vital statistics agencies, both from the standpoint of the present emergency and the long range outlook. Dr. L. J. Reed of The Johns Hopkins University is Chairman.

GONORRHEA GETS A PLACE IN THE VENEREAL DISEASE PROGRAM

FOR a great many years, gonorrhea was the foundling of anti-venereal disease effort: a wet-diapered and puny little bastard that would neither get well nor die. Scarcely anyone was willing to claim gonorrhea as a legitimate responsibility of the venereal disease program, for when health authorities spoke of venereal disease clinics they meant syphilis clinics; and when epidemiologists referred to tracing the source of a venereal disease they really meant tracing the source of a syphilis infection. It is true that there were a few voices crying for recognition of the seriousness of the problem of gonorrhea, but they got lip-service agreement rather than the action they urged; and whereas, at the clinic table, majestic syphilis sat at the head, plebeian gonorrhea occupied a place well below the salt.

This situation existed not because of a failure to recognize the public health significance of the disease, but was rather a defeatist attitude. The problem was too vast, the resources were too meager. Infection was widespread, treatment unsatisfactory, the end point of cure difficult to determine. Drugs administered came essentially under the heading of palliatives, and to believe that local treatment by injections of antiseptics was reasonably effective strained both the optimism of the therapeutic enthusiast and the credulity of the ignorant. This local treatment strained, too, the clinic staff. Irrigation of a case of gonorrhea is not a procedure that professional personnel enters upon with gusto. It is a dirty job, and time consuming, so, with few exceptions, attendance of cases of gonorrhea at the public clinic was not encouraged. This, perhaps, was just as well in view of the aphorism of Dr. Edward L. Keyes, quoted in a recent *Journal* article by John L. Rice: "The prime essential in the successful treatment of gonorrhea is to get the physician out of the urethra."

For purposes of argument, however, let it be recognized that an uncertain proportion of cases of gonorrhea became symptom free under the old treatment. There arose then the question of whether or not they were really cured. One had to rely upon direct smear which, while reasonably satisfactory in acute cases,

and fairly reliable in males, is not a productive method in determining the presence of the gonococcus in females, and is in all instances subject to the limitations of any direct-smear-microscopic examination. The same question of whether or not a case is still in a communicable stage continues to exist even though the treatment of gonorrhea has been revolutionized. Fortunately, sharper bacteriological methods are now available, and it is practicable for any good laboratory to run cultures on material suspected to contain gonococci. This culture method is not, of course, infallible. There have even been instances where, in material from the same case, the direct smear disclosed gonococci and the culture did not. The more usual outcome of controls of this sort, however, is that the culture picks up as positive about fifteen per cent of those cleared as negative by direct smear examination.

On the basis of this knowledge, most of the larger health departments and some of the smaller ones have shaped their procedures in release of persons known to have had gonorrhea, particularly in relation to the problem created when women are arrested on the euphemistic charge of "vagrancy." In San Francisco, the status of such women, as regards gonorrhea, is determined by culture. If positive they are isolated and treated. They may not be released in less than six weeks and then only on three successive negative cultures; in New York there is essentially the same procedure, except that there is no fixed minimum period of isolation: one might be released in less than six weeks if three successive negative cultures were obtained.

Thus, just as the newer sulfa drugs have replaced the cruder and less effective local irrigations in the treatment of gonorrhea, so is the culture method displacing the old and unsatisfactory direct smear procedure in determining the end of the period of communicability. These two reasonably satisfactory methods of handling this disease tend to place gonorrhea within the category of controllable diseases. And it is about time that this was done.

WHAT AND WHO IS AN EPIDEMIOLOGIST?

RECENTLY a colleague of ours was introduced to a Professor of Physiology. "And what is your particular interest?" asked the Professor. "I," said our colleague, "am doing research and teaching in epidemiology." "Ah, I see," observed the physiologist, "you are in the Department of Bacteriology." Again, and this time the clinician: "One cannot from cases reported to the health department learn the epidemiology of a disease. Such data will not include all cases, and will include non-cases. Exact epidemiological conclusions may be drawn only from the clinician's own observation." And then the statistician enters the argument with rigid references to comparability, probability, ranges, errors, correlations, and regressions.

In the circumstances, it is understandable if one asks, are epidemiologists born or made or just self-confessed? May the clinician, the statistician, the bacteriologist properly designate himself as an epidemiologist? Can one be an epidemiologist and something else besides? Does the first-hand experience of a quarantine officer take him within the fold? What about one who, in retrospect, studies the data of past epidemics; and the medical historian with intimate and detailed knowledge of the classic writings in epidemiology? One who concentrates upon a single disease—its laboratory, clinical, and epidemiological aspects—is he an epidemiologist in general or only in particular? May one not formerly an epi-

demiologist reach this state merely by being given responsibility for epidemiological work, or if once an epidemiologist is one always an epidemiologist? Is epidemiology a status that may be conferred by acclamation or announcement, and does portentousness of manner and mien tend to cause colleagues to accept one as an epidemiologist?

On the subject of what and who, and even why, is an epidemiologist, we invite letters to the Editor. Some of these letters might even be published.

IN THE SLUMS OF PUBLIC HEALTH IGNORANCE

GEDDES SMITH, in his admirable *Plague on Us*, provides a thriller touch in the titles he chooses for identification of certain epidemiological episodes: *The Case of the Ladylike Oysters*, *The Case of the Wading Boys*, etc. Perhaps this is a useful method for directing attention to other public health episodes, episodes which occur because of the cupidity or ignorance of man, and which illustrate the complexities of modern civilization. Here then, are samples of things that have arisen in what might be called the underworld of public health.

The Metallic Snuff Case—Some of our citizens, whose foreign background is pretty recent, prefer a European type of snuff, which has a greenish color. War conditions made it impracticable to import, and so a manufacturer achieved the same color effect by adding to native snuff some fifteen per cent of lead chromate, with the results that one would expect.

The Case of the Too-Shiny Forks—An easy way to make silver bright is to put it into a solution containing a dash of cyanide. Manufacturers, knowing this, put such a silver brightening powder on the market. Unfortunately, small portions of the powder sometimes stuck to the eating utensil, and from the ensuing cramps, diarrhea, and collapse, one concluded that the clams must have been bad. Huntington Williams explored this subject epidemiologically and now, in most places, the use of this polish is taboo.

The Mystery of the Necrosed Jawbones—Why did certain workers engaged in an industry important in World War I suffer from a mysterious illness, which eroded their bones and in a number of cases caused death? It was radium poisoning. Today, through periodic radon tests, luminous paint workers are protected.

Who Poisoned the Parson?—In the days of prohibition, fluid extract of ginger was a favorite and reasonably potent drink, and in some sections of the country there was a fine market for it. An enterprising manufacturer found that tricresyl phosphate could be substituted for the ginger component and would serve just about as well. It was cheaper, and on government test gave a result comparable to that of the ginger itself. And so this adulterated fluid extract of ginger went on the market. Among thousands of others, the preacher, who should have been above such things, drank the stuff in lieu of whiskey—and they all developed serious peripheral neuritis. Now, under food and drug regulations, cresyl phosphate may not be substituted for ginger.

The Curse of Cadmium—Housewives had become accustomed to aluminum kitchenware and refrigerator trays. When aluminum went into war production some manufacturers attempted to give to their products an aluminum or stainless steel appearance by plating them with cadmium. The illness that arose in a number of purchasers was a gastroenteritis: the type of thing which the public and some physicians erroneously call "ptomaine poisoning." Actually, it was

cadmium poisoning. At present there is no specific law against this use of cadmium, but the Office of Production Management will not in future release cadmium for plating food utensils.

Giovanni and the Almond Paste—If one eats a large number of almonds, he might take in enough prussic acid to get symptoms. Heat, however, breaks down this dangerous ingredient, so that paste made of almonds which have been subjected to high temperatures, as usually is the case, is all right. Giovanni and his playmates bought and ate great gobs of almond paste candy which, as it were, was in the raw. They didn't die but they were pretty sick.

Naturally, these are only a few of the many similar episodes which have occurred in recent years. One need not be astonished that they happen. It is remarkable that they are not more frequent and disastrous. Generally, as a matter of good business, to say nothing of common decency, those who were responsible for these things did not realize the danger or were careless. But there will always remain some who consider first the money to be made by a substitution here or an adulteration there and consider only secondarily, if at all, the havoc which may be wrought by such procedures. From time to time and in diverse places, evidences of their racketeering will come to light, but the swift recognition of the source and character of the trouble and the effective control measures taken in the past give encouragement that as new problems arise they will be dealt with promptly.

BOOKS AND REPORTS

Books of Special Interest to Public Health Workers

MAZÛCK P. RAVENEL, M.D.

*"That place that does contain
My books, the best companions, is to me
A glorious court, where hourly I converse
With the old sages and philosophers."*

JOHN FLETCHER

AGAIN we are offering a review of books along the lines of public health which have appeared during the year and which we consider of especial use to all workers in public health projects.

There have not been as many textbooks on matters concerning public health as usual. From some points of view this is regrettable but, on the other hand, so many new things have happened and are happening every day that, as pointed out under one heading later, an admirable textbook which has already undergone three revisions is behind the times in respect to the "blasts" which occur from aerial bombing.

While prevention is the watchword of an Association like ours, it has seemed wise to venture somewhat into the field of treatment. First aid, for example, is now one of the most efficient measures in the preservation of human life and the avoidance of crippling and exhausting consequences.

BIOGRAPHY AND HISTORY

This year has brought out a number of interesting and more or less important biographies. There are a number of histories bearing on medicine, including one monumental work on the history of medicine itself. From these we have selected: *A Surgeon's Life—The Autobiography of J. M. T. Finney*, Putnam, which contains much interesting history, principally of Johns Hopkins Hospital and its personnel. An interesting note is the story of the adaptation of the rubber glove for surgeons, now universally used. There is also an interesting story of the politics back of the appointment of one Surgeon General of the Army. Delightful reading, in spite of a New England opinion to the contrary. *L. Emmett Holt: Pioneer of a Children's Century*, by R. L. Duffus and L. Emmett Holt, Jr., Appleton-Century. The name of Holt is intimately con-

cerned with the history of child health in America, and in this review we have called attention to the 11th edition of his book on *Diseases of Infancy and Childhood*. This story of his life is sympathetically written by his son and a well known newspaper man. It will be welcomed by all who are interested in children's welfare. *Hugh Young: A Surgeon's Autobiography*, Harcourt, Brace. Biographies and autobiographies if honestly done are always interesting. "Lives of great men all remind us." Even though this quotation may not be entirely apt in the present instance, the book is beautifully printed, with colored plates, and in a style suitable "for handsome Hugh." *A Yankee Doctor in Paradise*, by S. M. Lambert, Little, Brown, tells a wonderful story of the conquering of hookworm in the South Sea Islands. It is recommended to everybody for its history, its anthro-

pology and its humor—delightful and informative reading for the overworked doctor. *Papers of Wade Hampton Frost, M.D.—A Contribution to Epidemiological Method*, edited by Kenneth F. Maxcy, Commonwealth Fund, is a part of the story of a man who had a great influence on the study of epidemiology in America, perhaps greater than any other one man, and who died entirely too soon. *A History of Medicine*, by Arturo Castiglioni, Knopf. There is always reason for the study of the history of medicine. This is an especially good book, well translated from the Italian by Krumbhaar, of the University of Pennsylvania. It is highly recommended to physicians, public health workers, trained or otherwise, and to general readers. *Man's Greatest Victory Over Tuberculosis*, by J. Arthur Myers, Thomas, is the story of the part the veterinary profession has played in the eradication of tuberculosis in cattle, a gigantic undertaking which seemed well-nigh impossible, but has been accomplished to an amazing degree. Incidentally, it tells the story of the constant improvement in the standards which have brought the veterinary profession to its present high standing. Indeed the author, who is a physician himself, and has made a special study of tuberculosis, says that human medicine is 40 years behind veterinary medicine in regard to tuberculosis control. In America, which probably leads all great countries in the purity of its milk supply, we have become so accustomed to accepting the high standards that we are apt to forget those who worked against great odds to bring this condition about. This book makes the history available to the public. *William Henry Welch and the Heroic Age of American Medicine*, by Simon Flexner and James Thomas Flexner, Viking Press, is an unusually intimate biography. In addition to his own history, it gives much of the histories of his various activities

including his work in the Johns Hopkins Medical School and Hospital and the Rockefeller Foundation. Elsewhere in this issue, an extensive review of the book appears.

CHEMOTHERAPY AND SERUM THERAPY

No outstanding work has come to our attention on this subject during the year. There have been numerous articles and considerable extension in the number of sulfur compounds and their use which can be found in the current literature.

CHILD HYGIENE AND TRAINING

There was a dearth of these books in 1940, and a still greater dearth during 1941. The literature abounds in references and short articles. We welcome *Holt's Diseases of Infancy and Childhood*, by L. Emmett Holt and John Howland, 11th ed. revised by L. Emmett Holt, Jr., and Rustin McIntosh, Appleton-Century. The author was a pioneer in and founder of preventive pediatrics in this country. His book has been standard from the first edition. It has now grown to 1,421 pages but no more authoritative work exists.

ENGINEERING

No outstanding work in this field has come to our attention during this year except *Sewage Treatment*, by Karl Imhoff and Gordon M. Fair, Wiley. This book was published in 1940 and reached us belatedly in 1941. It is a good and useful book at any time.

HOUSING

The housing problem in America is acute. There has been tremendous dislocation of homes and families. Immense industrial plants for munitions, airplanes, high explosives, tanks, etc., have sprung up in many parts of the country. Many, many millions of dollars have been spent for plants of all sorts. The builders of these move in on short notice, and their completion

will bring demands for thousands of homes for the operatives. Many articles and discussions have found their way into print, but it is apparently all too new to have found its way into books, with few exceptions, one being, *Industrial Housing in Wartime—Results of the Competition Organised by The Royal Institute of British Architects*, London. This is an authoritative book coming from the highest authorities in England after a prolonged study. The housing problem in America is already acute and there is every evidence it will be more acute when victory comes. This book contains a great deal of value for us in this country. Another exception is *Housing for Health*, by various authors, Committee on the Hygiene of Housing, American Public Health Association. This deals with housing codes, housing surveys, and slum clearance, particularly from the standpoint of the health officer, and with other matters of interest to both health officials and housing experts.

INDUSTRIAL HYGIENE

The many new endeavors which we have undertaken and the speed required make the subject of industrial hygiene of unusual importance. Again we can say that the literature is full of the subject but little has attained permanent form. The following are outstanding studies which have reached the book stage: *Manual of Industrial Health Hazards*, by Joseph B. Ficklen, Service to Industry. With the diversion of all forms of industrial work toward defense efforts, carrying with it the increased use of new and some comparatively unknown chemicals, this book is a reliable guide and experienced authority, especially useful because it is brief and to the point. *Sewage Treatment Works: Administration and Operation*, by C. E. Keefer, McGraw-Hill, is a timely and needful book, written with a definite purpose and showing careful planning

and execution. It is an up-to-date text and reference book, useful for professional engineers, state and municipal officials, plant superintendents, etc.

LABORATORY

While the Laboratory Section of our Association is large and active, owing to the conditions which have affected other departments, textbooks on laboratory procedure have been few, though many shorter articles are found in the current journals. Books which have been reviewed are: *Diagnostic Procedures and Reagents*, by various authors, American Public Health Association, is considered an indispensable addition to the library of practising bacteriologists and serologists. It is more comprehensive than the ordinary laboratory manual and more serviceable than some of the larger texts on laboratory methods. *Approved Laboratory Technic, Clinical, Pathological, Bacteriological, Mycological, Parasitological, Serological, Biochemical and Histological*, by John A. Kolmer and Fred Boerner, Appleton-Century, has been revised (3rd ed.) and brought up to date in most respects in 1941. Curiously, it is not up-to-date on the typing of pneumococci and in the section for the examination of milk. In spite of these defects it is a very useful and comprehensive manual of laboratory methods.

MENTAL HEALTH

Mental health has been drawing the increased attention of all health workers for some years past. The emergency increases its importance. The following books on the subject can be recommended: *Psychotherapy*, by Lewellys F. Barker, Appleton-Century. The assembling of large bodies of men in constricted areas with the necessary discipline of training invariably brings to the front a number of mental maladjustments. The conditions of actual

war subject men to mental and physical strains which present many problems. This book gives a discussion containing expositions and interpretations which are simple, terse, and readable. There will be much use during the next few years for this book, which is a personal and helpful treatise. *Mental Disease and Social Welfare*, by Horatio M. Pollock, State Hospitals Press, is the result of a long experience in handling mentally ill people by a sympathetic and practical man. Even in ordinary times, about 5.5 per cent of all people born may be expected to enter a mental hospital at some time in life. The proportion will be larger in such times as we are having. It is reassuring to note that many patients are restored to normal community life and that relatively few commit criminal offenses. These facts are evidence that our hospital methods are producing beneficial results not only to the patients but to the community.

NURSING

Never was there such demand for nurses, especially public health nurses. One has only to read the daily papers and medical journals to see the tremendously increasing demand for all types of nurses. *The Public Health Nurse and Her Patient*, by Ruth Gilbert, Commonwealth Fund, is an epochal book marking a long step forward in the development of nursing and can be read and re-read. It is recommended not only for nurses but for health officers and their medical staffs. *Communicable Diseases*, by Nina D. Gage and John Fitch Landon, Davis, is an excellent, up-to-date book for nurses, which one reviewer says is "the most usable book this reviewer has seen on this subject." Already there are reports of an increasing incidence of tuberculosis which might be expected. However, it emphasizes the importance of books on its prevention and control, and proper

nursing of the disease itself. *Tuberculosis Nursing*, by Grace M. Longhurst, Davis, is an excellent book written for student nurses, but invaluable to nurses generally for reference. If history repeats itself there will be entirely too much use for a book of this sort before our troubled world can smile again. *Nursing in Prevention and Control of Tuberculosis*, by H. W. Hetherington and Fannie Eshleman, Putnam, is another excellent study on nursing in tuberculosis, especially recommended for those who have had little or no special training in this field.

NUTRITION

We are again being bombarded with slogans concerning nutrition, and terrible pictures of our population allegedly brought about by improper feeding. The current literature is overcrowded with articles on nutrition in general. The majority of these add nothing to our knowledge. It looks as though every little first course student in home economics feels impelled to take part in the barrage, and we have developed a new word, "nutritionist," which is enough to make any lover of good English scream. Frankly, while our advice has not been asked, we believe that one good standard book, such as those recommended below, is worth hundreds of the fly-by-night articles which are now afflicting our eyes. *Dietetics Simplified: The Use of Foods in Health and Disease*, by L. Jean Bogert; Laboratory Section by Mame T. Porter, Macmillan, is now in its second edition, and has been most favorably reviewed as being practical and thoroughly scientific, and, on this account, of service to home economics students, hospital dietitians, public health nutritionists, nurses, and medical students. *Essentials of Nutrition*, by H. C. Sherman and Caroline Sherman Lanford, Macmillan, is a readable and adequate review of the essentials written especially for laymen who

wish to understand the relation of food to health. It is useful for all classes of readers. *Chemistry of Food and Nutrition*, by H. C. Sherman, Macmillan, is a sixth edition of a standard book which has been brought up to date, and can be recommended.

ORAL HYGIENE

Oral hygiene is still in the picture. Everyone recognizes its importance in nutrition and in general health, but in spite of many discussions and some experimental studies of high order, we seem as far from a knowledge of some fundamentals, especially those concerning the decay of teeth, as we were nearly a hundred years ago. We can only state that conditions seem to be improving. Only one book has come under our observation which can be recommended: *Your Teeth: Their Past, Present, and Probable Future*, by Peter J. Brekhuis, University of Minnesota Press, is timely and excellent, a challenge to dentists to look upon their problems from a broader point of view. The last chapter, "How We Can Save Our Teeth" will be of special interest to the general reader. Despite the fact that none of the controversial points concerning dental caries are cleared up authoritatively, the book is an important contribution, especially in showing the relation of dental diseases to public health, in particular that phase of it relating to nutrition.

PUBLIC HEALTH

There has been the usual crop of reports from state and city health departments, most of which are more than a year behind time. During the year very few books under this heading have come to our attention, though much can be found in current literature which might be put under this classification. *The 1940 Year Book of Public Health*, edited by J. C. Geiger, Year Book Publishers, is an excellent review of the

literature on public health, up to date, and presented in a handy volume—most useful. *Rheumatic Fever: Studies of the Epidemiology, Manifestations, Diagnosis, and Treatment of the Disease During the First Three Decades*, by May G. Wilson, Commonwealth Fund. This is an excellent study of that puzzling condition with its many aspects which ranks as the third most important of the chronic infectious diseases, so presented that it can serve both as a textbook and for reference.

TEXTBOOKS AND NEW EDITIONS

Few textbooks have come to our attention during the year, but a number of new editions of standard works have appeared. It does not take long for a textbook on public health to become obsolete these days, though of course many fundamentals must remain the same. *Bacillary and Rickettsial Infections: Acute and Chronic, Black Death to White Plague*, by William H. Holmes, Macmillan, is the result of 27 years' experience, and, though written primarily for medical students, it is written with such simplicity and lucidity that it should appeal to a wide range of readers. The increasing importance of the rickettsial infections has been recognized. *Public Health Administration in the United States*, by Wilson G. Smillie (2nd ed.), Macmillan, has been enlarged, improved, and brought up to date. It is notable for its clarity and precision. The book has made a place for itself in public health literature. *Manson's Tropical Diseases*, edited by Philip H. Manson-Bahr (11th ed. rev.), Williams & Wilkins, needs simply an announcement. It should be found in the library of every agency and student concerned in the field of medicine and public health, especially in warm climates. *Introduction to Parasitology: With Special Reference to the Parasites of Man*, by Asa C. Chandler (6th ed. rewritten and enlarged), Wiley, needs

only a mention as it has been standard since the first edition 22 years ago. This last edition, up-to-date, should receive an enthusiastic reception by students and teachers of parasitology and public health workers. *Preventive Medicine*, by Mark F. Boyd (6th ed.), Saunders, is an excellent reference and one of the best of its type. *Diseases Transmitted from Animals to Man*, by Thomas G. Hull (2nd ed.), Thomas, has been brought up to date and considerably improved over the first. It is not entirely sound in its consideration of the amount of pulmonary tuberculosis in human beings due to the bovine type of bacillus, but, on the whole, it is a most useful and practical book, especially in the present emergency. *The Avitaminoses*, by Walter H. Eddy and Gilbert Dall-dorf (2nd ed.), Williams & Wilkins, will serve as an excellent guide in this bewildering field of nutrition for the busy practitioner or health officer. The knowledge of few subjects has grown more rapidly than that of the vitamins, so that this second edition of a standard book is welcome. It is up-to-date, giving us the chemistry of vitamin K, and tells of the synthesis of B₁, etc. *Public Health and Hygiene*, by Charles F. Bolduan and Nils W. Bolduan (3rd ed.), Saunders, is a text filled from cover to cover with useful information, condensed, free from padding, and appropriate for its intended field.

MISCELLANEOUS

Under the heading of Miscellaneous we have included a number of books which might perhaps be classified under more appropriate headings. Classification of such books is largely a matter of one's judgment. Some books touch on so many fields that it is hard to place them in a restricted category. *The Virus: Life's Enemy*, by Kenneth M. Smith, Macmillan. While it is not clear for what class of readers this is intended, and it has a number of faults,

the author has summarized a large amount of material in a thought-provoking manner. Virus diseases are attracting much attention and threaten the welfare of man, animals, and plants. There are few more important subjects. *The Parasites of Man in Temperate Climates*, by Thomas W. M. Cameron, University of Toronto Press. With the wide distribution of our Army and Navy, as well as civilians, this brief and authoritative presentation of the parasites which not only plague but produce disease in the human body is timely. Books of this type are often more generally useful than the more profound treatises on the same subject. *Tuberculosis and Genius*, by Lewis J. Moorman, University of Chicago Press. Tuberculosis affects our lives from so many different angles that anything concerning it is of interest. This is a discussion which will hold the reader's attention and doubtless give courage and inspiration to most of those afflicted with the disease as well as promote tolerance and sympathy in those who come in contact with them. *The Streptococci—Their Descriptions, Classification and Distribution, with Special Reference to Those in Milk*, by William D. Frost and Mildred A. Engelbrecht, Willdof Book Co., is an excellent study, which although not entirely orthodox in certain respects, has done much to simplify the study of milk from the hygienic standpoint, but also shows the necessity for further investigation as to the classification of streptococci. *Plague on Us*, by Geddes Smith, Commonwealth Fund, is a book on epidemiology for laymen, written by a layman. It is recommended to all thoughtful and intelligent laymen, and even suggested as required reading to all introductory in epidemiology. It was the principal selection of the Scientific Book Club for February, 1941. *A Symposium on Human Malaria*, edited by Forest Ray Moulton, Science Press Printing Company, is a

systematic, comprehensive, authoritative and thoroughly documented discussion of the problems of human malaria in North America and the Caribbean region.

BOOKS ESPECIALLY USEFUL AT THIS TIME

In view of the emergency we have gone somewhat afield. We have pointed out in explanation of the inclusion of certain works on treatment that first aid and emergency treatments were great factors in hindering such bad results as prolonged convalescence, deformities, and even fatal issues. It has occurred to us that it might be useful to put under one heading a number of well worth while books which war has made of especial importance this year. While some of these books are technical and are recommended almost exclusively to those with training in certain medical specialties, there is no doubt that a wider knowledge of prevention in all conditions of warfare will be of assistance in maintaining confidence and in the proper direction of effort. *Health and Efficiency of Munition Workers*, by H. M. Vernon, Humphrey Milford. The author of this book is a pioneer in such studies and has served for a long time as an investigator of the Munitions Workers Committee and Industrial Health Research Board of Engineering. It should be of great value to us in this country, keyed up as we are, to war production. *Lectures on War Neuroses*, by T. A. Ross, Edward Arnold. These lectures are recommended as being especially clear and well put, of value both to civilian physicians and to those in the Army or Navy. *Veneral Diseases*, by E. T. Burke, H. K. Lewis, is an especially good guide for diagnosis by an author of wide experience. *Medical Diseases of War*, by Sir Arthur Hurst, Edward Arnold. Based on the author's experience in the R.A.M.C. during World War I, the value of the

book led to a revision in 1918. It has now been brought up to date as far as possible, but already requires some further revision to take care of the "blasts" due to bombing. The book is authentic throughout and contains pioneer studies on the functional nervous disorders. *Scabies—Civil and Military—Its Prevalence, Prevention and Treatment*, by Reuben Friedman, Froben Press, is called a "Sign of the Times." From 1914 to 1918 skin diseases were responsible for 90 per cent of the illness in the Army. It is an admirable book and considered an outstanding contribution to a matter of growing importance. It contains a good history of the disease and states that Napoleon was a victim of scabies. *Medical Problems of War*, by Hugh Clegg, J. M. Dent and Sons. This is short and non-technical and written for laymen under war conditions. It also touches on post-war planning. *Cambridge Evacuation Survey: A Wartime Study in Social Welfare and Education*, edited by Susan Isaacs, Methuen and Co., is an excellent study, though it must be remembered that the whole problem is in a kaleidoscopic condition. Certainly the experience of England in this respect must be of value to us in this country. *Military Medical Manual*, Military Service Publishing Co. (4th ed.). The great increase in the medical personnel of our Army due to the present emergency makes the appearance of the 4th edition of this excellent manual timely and welcome. *The Officers' Guide: A Ready Reference on Customs and Correct Procedures Followed Within the Army Which Pertain to Commanding Officers*, Military Service Publishing Co., is for the use of all officers of the Regular Army, National Guard, and Officers' Reserve Corps. In spite of the terrible title, this is a very useful book. It goes much further than telling the officers of the various branches of the service how to

conduct themselves on all occasions. There are valuable sections on personnel, keeping fit, etc., all of which pertain to the health and morale of a corps. It is an excellent book and most timely. *Special Surgery in War Time*, by D. W. C. Northfield, Eyre and Spottiswoode, contains the combined wisdom and experience of five authors. The entire book is short, the articles are brief, authoritative, and preëminently practical. It deserves the highest praise. *Surgical Nursing*, by E. L. Eliason, L. Kraeer Ferguson, and Evelyn M. Farrand (6th ed.), is "everything a textbook should be: clear, concise, well illustrated." It is especially timely. *Air Raid Precautions—First American Edition*, Chemical Publishing Co., Inc. It is not a comfortable thought that this book must be recommended. It is an English work published for Americans. So many factors concerning health are involved which are of direct concern to those who are evacuated or must seek air raid shelters, to say nothing of the surgical accidents which occur, that this book is timely, written in the light of the devastating experience of the English. *Emergency Surgery*, by Hamilton Bailey, Wm. Wood (4th ed.), has had three editions and two reprints since 1930. It is extremely comprehensive and covers emergency surgery in a remarkably able manner. *Medicine Versus Invasion: The Home Guard*

Medical Service in Action, by G. B. Shirlaw and Clifford Troke, Secker and Warburg, is a most stimulating book and the time of its appearance is appropriate. While this review is being written, the radio and newspapers are telling us of American ships being torpedoed in sight of our shores, both the Atlantic and Pacific, incredible but true. *Warwick and Tunstall's First Aid to the Injured and Sick*, edited by Norman Hammer, John Wright and Sons, is an advanced ambulance book, full of excellent suggestions and explanations. The authors consider it wise to teach the greatest number of people possible the simplest common sense facts that tend to save life—a timely and excellent book. *Tropical Tips for Troops*, by E. T. Burke, W. Heinemann, is intended both for officers and men, and is recommended for the reading of those who are about to go on military expeditions. The English review says the book will be in great demand for such purposes. It is equally certain that our men will be exposed to the tropics throughout a large part of the world, and the book should be useful for them. *Organization, Strategy and Tactics of the Army Medical Services in War*, by T. B. Nicholls, Williams & Wilkins (2nd ed.), is written for the British Army, but should be most useful for Americans. It covers a wide scope and fills a long-felt need.

Teaching Preventive Medicine to Medical Students—With Special Reference to the Use of Health Department Facilities—By Hugh R. Leavell, M.D., Dr.P.H. New York: Commonwealth Fund, 1941. 77 pp. Price, \$.25.

This is a valuable monograph. It contains much factual data which have been obtained by both observation and correspondence. Its purpose is to determine the use of health department

facilities for teaching medical students. This has been well done. It includes personnel, methods of instruction, organization, publications, and summaries.

The author presents about three pages of conclusions based on the study. These represent analysis of the data which were obtained. There are also 65 valuable references on the subject of teaching preventive medicine and public health to medical students. It seems to

me adequate safeguards were used in analyzing the data. The points of view expressed are dependable.

This study is particularly significant because

1. It presents a record of present health organizations and administrative practices with reference to instruction of students.
2. It presents details and summaries of qualified opinion concerning relative values and needs in teaching preventive medicine.
3. It considers the interests of both the medical school and the official health agency.
4. It presents in one publication selected extracts from the literature and a well chosen bibliography for those engaged in teaching.

The author is to be congratulated upon the completeness of the investigation.

W. S. LEATHERS

The Principles of Dairying—By Henry F. Judkins. Revised by Merrill J. Mack (3rd ed.). New York: Wiley, 1941. 315 pp. Price, \$3.00.

This is a revision of a standard college introductory text in dairying. The earlier editions of this text dealt chiefly with milk production. The present volume includes additional new chapters on butter making, ice cream making, cheese making, and miscellaneous dairy products. These chapters in a brief concise manner present manufacturing procedures, formulae, and typical computations related to producing a great variety of cultured and frozen milk products. The discussion on ice cream making is presented in detail.

The book as a whole can be said to be intended for students or others entering into dairying or the manufacture of dairy products. Although not specifically a work prepared for public health workers or those concerned with the sanitary supervision of milk and milk products, these workers may find it useful to have at hand the descriptions and discussions of the many processes and of the machines used in making milk products which this book contains.

SOI. PRINCUS

Edith Cavell—By Helen Judson. New York: Macmillan, 1941. 288 pp. Price, \$2.50.

Here is a timely book that will have great popular appeal, not because it is the story of a splendid nurse but because of the tragic end to her career as a zealous patriot.

It was George Bernard Shaw who referred to Edith Cavell as a heretic in his "St. Joan," thus provoking the curiosity of this author to learn more of the personality of the real woman known as a martyr to national patriotism. However, one gathers from the documentary evidence produced that it was not martyrdom but rather an overmastering desire to aid helpless humanity which stimulated her actions. In a last letter to a friend she wrote, "I want you to know I was neither afraid nor unhappy to give my life for England," and again to her pastor, "I have nothing to regret—if I had it to do over again, I would do just as I did."

Fortunately Miss Judson completed her research for this book in 1939, reading the last document but thirty-six hours before the outbreak of the Second World War. The evidence diligently accumulated permits her to write most convincingly of this extraordinary woman.

Over one-third of the book deals with those tragic events of 1915, ending with the death of Edith Cavell at the Tri National. The rest is devoted to the life and character of a great personality.

Historians previously have touched but lightly on the fact that the gentle, kindly, puritanical Englishwoman, Edith Cavell, was the founder of modern nursing in Belgium. At the request of Dr. Antoine DePage in 1907 she established the school now known as L'Ecole Edith Cavell—Marie DePage. From those early beginnings rapid advance was made and many notable women throughout the land have followed in her footsteps and given life to Belgium.

The story, serious and earnest, is well told, having an appreciation for minor humorous situations and making interesting reading while it makes a definite contribution to the history of nursing.

The dust jacket bears a reproduction of the bronze medallion on which appear the profiles and names of Edith Cavell and Marie DePage, the gracious wife of the blustering Dr. DePage who lost her life in 1915 on the *Lusitania*. One does not see the reverse side on which is cast the one word, "Remember." Its implication makes one agree with Miss Cavell that, "Patriotism is not enough." All must have patience and courage, but over and above, understanding of our fellowmen—at this time.

HAZEL A. GOFF

Organization and Administration of Group Medical Practice — By Dean A. Clark, M.D., and Katharine G. Clark. *New York: Joint Committee of the Twentieth Century and the Good Will Fund; and Medical Administration Service, Inc., 1941. 109 pp. Price, \$.25.*

Issued as one of a series of four pamphlets on the policies and procedures of group health plans, this 109 page booklet will be of interest to physicians and administrators concerned with the management of clinics in general. The authors studied fifteen clinics in different parts of the country. Some of these were connected with leading medical schools; others were private group clinics, the Mayo being one; still others were private, coöperative, or industrial clinics which supply all or part of their service on a prepayment basis.

Out of this experience there was formulated a set of principles and procedures for group medical practice which were previously published under the auspices of a committee of well known physicians. The pamphlet works out in detail the application of these principles in the day-to-day activities of clinics. It directs needed attention to the pro-

fessional, as distinguished from the financial and engineering aspects, of furnishing medical services through an organized group of physicians instead of through doctors working individually in private offices.

As the authors point out, the term "group medical practice" has been commonly applied only to private clinics of the Mayo type, but has a much wider application. The staffs of well organized hospitals and out-patient departments represent a large-scale and increasing area of group practice. An interesting section on appraising the quality of service merits attention, although it is only a beginning in a difficult field. Health departments are more and more involved in clinic services and in coöperation with hospitals and out-patient departments. From this point of view as well as from those of the hospital administrator and the clinician, this pamphlet is timely.

MICHAEL M. DAVIS

The 1941 Year Book of Public Health—*Edited by J. C. Geiger. Chicago: The Year Book Publishers, 1941. 544 pp. Price, \$3.00.*

Dr. Geiger has prepared a very excellent summary of the important contributions in the field of preventive medicine and public health for the year 1941. He has, in most cases, added an editorial comment of his own, expressing the opinion of one who has had long years of experience in the fields of public health administration and epidemiology.

The current year book is especially timely as it deals with the literature of many exotic diseases, which will increasingly become a concern of all health officers. With the movement of our troops into tropical and sub-tropical areas, new problems in communicable disease control immediately present themselves. All public health administrators should keep abreast with war problems as they arise, and in this *Year*

Book will be found short, concise and timely reviews of current literature.

This book should be on the desk of every public health worker who has administrative responsibilities.

HENRY F. VAUGHAN

The Value of Health to a City—Two Lectures Delivered in 1873 by Max Von Pettenkofer, M.D., Translated from the German by Henry E. Sigcrist, M.D. Baltimore: Johns Hopkins Press, 1941. 52 pp. Price, \$1.00.

Great names in medical history are, for the most part, of men who have contributed greatly to the medical sciences. They are of anatomists, physiologists, pathologists or bacteriologists, who conducted research and made discoveries; or they are of physicians or surgeons who gave classical descriptions of diseases or performed great operations; or perhaps they are of men from related fields such as chemists, physicists, or biologists who contributed to the medical sciences.

There are, however, a few names of men who owe their places in history not to such specific deeds. Perhaps, and often, they were great scientists or physicians, but we do not know them primarily for their discoveries or scientific contributions. Certainly in this country our own Dr. Welch was such a physician; perhaps Hippocrates belonged in this group; indeed Pettenkofer was great beyond his scientific attainments.

It is difficult to state just why such men were great; just what they did to earn for themselves a place in history. But on this particular point we are greatly indebted to Dr. Sigerist for his translation of Pettenkofer's two Public Lectures given in 1873, entitled "The Value of Health to a City," which affords us an unusual view of the real caliber of the man. In this we see the breadth and scope of his vision; we see him viewing the sum total of disease and ill health in the whole community—

in the mass—and the toll it is taking; and we see him marshalling his forces, not only medical, but of all science, to control, to prevent disease. We see him striving for a proper place for health—for medicine—in the community, in the political economy. In fact we see Pettenkofer as a statesman, a medical statesman.

J. S. CHAMBERS

Refuse Collection Practice — By the Committee on Refuse Collection and Disposal. Chicago: American Public Works Association (1313 E. 60th St.), 1941. 659 pp., 221 ill., charts, tables. Price, \$5.00.

This volume is the first comprehensive treatise on this important service published since 1921. It is the result of almost two years' research on the part of the Association and it presents an analysis and appraisal of refuse collection practice based upon information from 190 cities of the United States and Canada. The book also contains detailed tabulations of practices, cost data, a selected bibliography, and is completely indexed. ARTHUR P. MILLER

Standard Methods for the Examination of Dairy Products (8th ed.). New York: American Public Health Association, 1941. 288 pp. Price, \$3.00.

Laboratory workers concerned with milk and milk products already being thoroughly familiar with this volume, the reviewer addresses his comments to others who, like himself, are neither bacteriologists nor chemists but interested in milk sanitation and in broadening their mental horizons.

This edition is the culmination of at least 36 years of continuous study and effort by a gradually increasing group of workers for whom it has been a labor of love. Much of it, naturally, is too technical to be clear to readers not experienced in laboratory fields. The administrator, however, will be making

a mistake if he lays it aside on this account. He will find the historical introduction interesting and enlightening. Even the text covering technical matters is interspersed with information he should have concerning the use and limitations of various tests, and it is presented in simple and understandable language. The administrator should read it as he should his Bible, content to understand what he can.

The story opens, appropriately, with discussion of the bacteriological methods the development of which marked the beginning of progress in milk sanitation. It ends with the relatively new, epoch-making phosphatase tests. With proper conservatism these are held still to be tentative.

PAUL B. BROOKS

Water Purification for Plant Operators—*By G. D. Norcom and K. W. Brown. New York: McGraw-Hill, 1942. 180 pp. Price, \$2.50.*

This is an instruction book which will serve to aid water purification plant operators to perform their routine duties. Requirements of a modern water supply and the various methods and steps in water purifications are covered. Other sections on records, the care of the plant, its equipment and appurtenances, and laboratory control add to the book's value. Briefly and simply, both theory and practice are discussed. Self-examination questions are to be found at the end of each chapter.

ARTHUR P. MILLER

William Henry Welch and the Heroic Age of American Medicine—*By Simon Flexner and James Thomas Flexner. New York: The Viking Press, 1941. 539 pp. Price, \$3.75.*

One approaches the review of this book with considerable diffidence. Perhaps the task would be easier for a reviewer who had not known the subject.

For many years Welch was known as the dean of American Medicine. No

medical man had a wider acquaintance than he, and every younger man felt it was an honor to meet him. This volume then will be widely welcomed since it carries the story of one so widely known, so much admired, and so much loved personally.

The story of Welch's life carries surprises. Coming from a line of medical men, and the son of an old-time country doctor, it is strange to hear that Welch had no taste for medicine, and dreamed of being a professor of Greek. While at Yale he was filled with theological reasoning. Incidentally, at that time, 1866-1870, Yale had only eight full professors, and during Welch's sophomore year a "radical innovation"—a course in French—was introduced. In this atmosphere Welch showed religious inclination and was intimate with the theological students. However, he finally decided on medicine, and in 1872 entered the College of Physicians and Surgeons in New York. His interest in medicine was due more to the personality of some of his teachers than to the subject, and he attributed his subsequent interest in pathology to Seguin's lectures on nervous diseases. In 1875 he was graduated, and in April, 1876, he sailed for Europe on a "voyage of exploration." An endless scientific curiosity led him to many of the best teachers of the day, so that in 1878 he returned to America with a "revelation" which he passed on to America during the rest of his life.

Among the many laboratories visited was that of Theodor Kitt at the Veterinary School in Munich, where he was astonished at the abundance of material and learned much concerning diseases of animals, and especially those which were common to both man and animals. He seems to have been the first American doctor to realize the relationship between human and veterinary medicine. In spite of this, it appears that Welch was somewhat slow in recognizing the

importance of bacteriology, though in 1884 he expressed the opinion that for some years the relation of bacteria to disease would be the most important subject in pathology. Incredible, but only "after weeks of heart-rending negotiation" did Welch obtain a laboratory at Bellevue, with no resources for teaching bacteriology — barely enough for his courses in pathology. His great opportunity came when he accepted the professorship at Johns Hopkins University. There he was one of "The Big Four," immortalized as "The Four Doctors" in the famous painting by John Singer Sargent. There is little question that his influence in the formation of the Medical School at Johns Hopkins was predominant. He founded modern pathology in America on lines which he had brought from the great teachers of Europe, and excited a widespread interest in it, which still exists. Indeed the charge has been made, perhaps with a degree of truth, that the patient has been neglected in favor of the pathological aspects of his case. Osler was, of course, the dominant medical man and introduced methods of teaching which brought the student in direct contact with the patient, counteracting to a great extent the trend which emphasis on the purely scientific aspect of disease had engendered.

It would be impossible to write of Welch without including much of the history of the Johns Hopkins Medical School and Hospital. This of course brings in John S. Billings, who designed the buildings and who Welch considered one of the wisest men he ever knew.

Many other prominent men of that time are mentioned, but the story is of Welch, and there is much more that one would like to say about him than can be contained in a review.

The Rockefeller Institute for Medical Research, with its world-wide activities long had the benefit of his advice, and again he was a dominant figure in its

multiple activities. One thing which impressed him much in Germany was the hygienic institute in Munich, and this seemed, more than any other one thing, to awaken in Welch an interest in hygiene and public health, in which he was active throughout his life. When the first World War came Welch hurried to Washington and offered his services. Throughout he had a seat in the Surgeon General's office, and there is no doubt that the wise things done in the medical services of the Army were largely due to his influence and advice.

The campaign against antivivisection begun in 1890 occupied Welch's attention to a great extent. Between 1896 and 1900 the antivivisectionists were rampant and in the Senate they had an advocate in Senator Jacob H. Gallinger, of New Hampshire, a homeopath of the old school. Welch gave up much of his time to fighting this legislation. W. W. Keen, of Philadelphia, another great man who was active in this fight, deserves much credit which is not given.

Any biography of Welch must give, as this does, much of the histories of his various activities. In addition to his work in the Johns Hopkins Medical School and Hospital and the Rockefeller Foundation, he played a large part in the service of the Red Cross, taking part in the Conference at Cannes in 1919. He had a great love for the history of medicine, and brought about the foundation of the Welch Memorial Library, buying books for which he spent many months in Europe. He founded the Johns Hopkins School of Hygiene and Public Health, was on innumerable boards and commissions, and was called upon for advice in many other ways.

There are Appendices, giving lists of the organizations to which he belonged, and honors bestowed. The book is well documented, some 59 pages being given to references. Throughout, the English spelling of words like connexion, colour,

favour, etc., is used. This is not in accordance with the best American usage.

Only a few personal remarks can be made, though one would like to speak much more of a man who was so universally loved. He was an early advocate of the historical method of teaching. As he expressed it, "the best line of approach to whatever subject he is teaching is really the historical one, not to formulate the existing line, but rather the way knowledge came to be." Another great teacher, Victor Vaughan, held almost identical ideas. Welch liked the German method of teaching and expressed the opinion that "students in American medical schools suffered from overteaching." Spoon-fed pupils seldom develop originality or scientific backbone. Welch did service in standing for correct English, and in his editorial work would frequently cut a paper to pieces, only to find sometimes that the ignorant author would change everything back to its incorrect form. Until very late in life, indeed only when he was in the hospital during his last illness, did he learn the use of a secretary. There exists a voluminous mass of correspondence in longhand. How he accomplished it all is a wonder. He did not write out addresses, but often appeared with a number of sheets, apparently manuscript, though only the top page would show a few notes. His language was exact and fluent. He never failed to hold his audience and to give the meat of a subject. His good nature and kindness led him into errors. When having promised some favor he could not conscientiously carry out, he put the matter out of his mind, and did not answer letters or even telegrams concerning the matter. When tackled by the unfortunate who did not receive the favor promised, he would, with his disarming smile, blame it on his absent-mindedness. There is reason to believe that he carried this somewhat further than is told in the book.

Altogether, this biography is an unusually intimate one. There were many contradictions in the life of Welch. In spite of his being a delightful companion, welcomed at every meeting, scientific or social, in spite of the delightful dinners he gave at the Maryland Club and elsewhere, his own letters show that he was often lonesome. He had no confidant except his sister. These facts are recognized by the authors, as shown by the closing sentence of the book: "Popsy, the physician who had been so greatly beloved, died as he had lived, keeping his own counsel, essentially alone." MAZÛCK P. RAVENEL

Stitt's *Diagnosis, Prevention and Treatment of Tropical Diseases—By Richard P. Strong, M.D. (6th ed.). Philadelphia: Blakiston, 1941. 2 Vols., 1747 pp. Price, \$21.00.*

The timely appearance of a new edition of this standard American textbook on Tropical Diseases is particularly welcome to all who are interested in this field of medicine, which is so important to our national defense in the present war. No happier selection of an editor by Admiral Stitt could have been made than the Professor Emeritus of Tropical Medicine of Harvard University, who has been a leader in so many of the advances in this field during the past forty years. With the coöperation of members of the Department of Tropical Medicine at Harvard, as well as members of the Army and Navy Medical Corps and other American authorities, Admiral Stitt's book has been almost entirely rewritten and has been expanded to meet present needs and to include prevention as the present title indicates.

Volume I contains sections on diseases due to protozoa and to bacteria; Volume II contains sections on diseases caused by filtrable viruses, rickettsiae and allied organisms, on nutritional disorders, on other miscellaneous diseases

such as heat stroke and heat prostration, tropical ulcers, granulomas and other skin diseases, and psychoses; diseases due to fungi and poisonous plants and diseases caused by helminths, arthropods and other poisonous animals. There is also a section on Medical Practice in the Tropics and Cosmopolitan Diseases, and an Appendix containing sections on Clinical Diagnosis, Laboratory Procedures and Hygiene in the Tropics. The work is profusely illustrated with colored plates, photographs, line drawings, maps and charts. Each chapter is followed by a list of important references and there is a complete index. The work is excellently printed on glossy paper but is rather lightly bound for the heavy use which it is likely to receive. Its length and cost are well compensated for by the breadth of its treatment of this field of medicine in which so many important recent advances have been made. It should be in the possession of every medical and public health library, every teacher of medicine and public health, every medical unit of the armed forces, and every physician and scientist interested in the field of tropical medicine.

HENRY E. MELENEY

Attention to Your Health — By Ernest I. Stewart, Jr. New York: Bureau of Publications, Teachers College, Columbia University, 1941. 82 pp. Price, \$.35.

Common facts about personal health as applied to life in the Army are presented in understandable form in this handbook. It is the second of three pamphlets prepared to assist young men in anticipation of selection into military service. Under twenty-five chapter headings, beginning with *Your Health*, ending with *Off Duty*, and including *Eating Out*, *Sniffles and Sneezes*, *Veneral Disease Facts*, and *the Eyes Have It*, the author succeeds in bringing together in concise form a wealth of information much of which may be new

to a recruit and all of which is worthy of review by him. The preparation of the book was sponsored by the National Committee on Education and Defense of the National Education Association and the American Council on Education in coöperation with the Pre-Induction Education Committee of Teachers College, Columbia University.

IRA V. HISCOCK

Keeping Safe and Well—By C. E. Turner, Frances W. Clough, and Grace Voris Curl. Boston: Heath, 1941. 214 pp. Price, \$.72.

Growing Up—By C. E. Turner and Grace T. Hallock. Boston: Heath, 1941. 216 pp. Price, \$.72.

These two books are a part of a new six book health series for grades 3 to 8. Like their predecessors, the *Malden Health Series*, they incorporate many of the principles resulting from experimental studies in health education made by the authors.

Using the story approach, the authors take their readers on trips which bring out a host of meanings of importance in health education. What youngster, for example, could fail to enjoy the delightful story associated with the "Pet Show," or thrill at the prospect of observing biological "Friends and Enemies" as seen through the magnifying glass. The authors have succeeded not only in telling their stories well but, more important, they have managed to integrate problems of health and safety into ordinary life situations without making it appear obvious. Subject matter has been organized entirely on a unit basis.

These books are nicely bound, attractively prepared, authentic, and well illustrated. Of especial value to the teacher is the inclusion of a list of additional books—"Stories to Read"—which may be needed to supplement their contents. The incorporation of a list of "Words to Know" is most commendable.

The reviewer recommends these books very highly. They will undoubtedly take their place alongside of other successful contributions of their kind made by the authors in recent years.

EARL E. KLEINSCHMIDT

The American and His Food—By Richard Osborn Cummings. Chicago: University of Chicago Press, 1940. 267 pp. Price, \$2.50.

While working on a history of the American ice industry and the development of refrigeration, Professor Cummings sought, but was unable to find, a systematic account of food habits during the past century. His book was written to make good this deficiency. Beginning with food on the farm and menus in the city in 1789, when city dwellers, like country folk, suffered from the lack of milk, fresh fruits, and vegetables, he carries the record through to 1940 when federal feeding programs reached their highest development in school lunches, the food stamp plan, and the distribution of cheap milk. The chapter on "Waging a War (1917-1929)" is of particular interest at the present time, for as the war of 1914-1918 helped many in this country to achieve a more balanced diet, so the present war may greatly speed progress toward the goal of diets adequate for health for the lower income groups. Professor Cummings deals throughout with the influence of social and technological forces on the national diet. He describes current advances in the science of nutrition in a running commentary which serves the reader as a useful frame of reference. His book is no mere compilation of data, but an attempt to appraise and to explain factors which were responsible for deficiencies and improvements in the diets of the American people. The book is pleasantly written, not without elements of humor, and gives evidence of wide and critical reading. I found the earlier

chapters more absorbing than those dealing with the postwar years, but this may be accounted for by the difficulty for reader as well as author of viewing current events in proper perspective. Professor Cummings's own point of view is illustrated by the following quotation: "The science of nutrition may be said to have advanced to the point where it is firmly established not only as a branch of preventive medicine but as a major instrument of social policy" (page 230).

This book may be recommended to physicians, health workers, nutritionists, nurses, and intelligent readers of all classes.

There are some interesting illustrations and a good index.

FRANK G. BOUDREAU

Community Hygiene—By Smiley and Gould. (3rd ed.) New York: Macmillan, 1941. 448 pp. Price, \$2.50.

Streamlined, abreast of the times, and supported by well chosen and in most instances, modern illustrations, the 1941 revision of *Community Hygiene* by Smiley and Gould will be valued by public health students and workers alike. The general field is well covered, the basic information is accurate, and the method of presentation is attractive. Bibliographies reflect careful choice.

The section on sanitary significance of the soil emphasizes in a new way the nitrogen cycle and portrays the soil as man's most efficient scavenger. Other sections, including the relationship of weather to health, the public health aspects of heart disease and cancer, industrial health, and the economics of health are indicative of the broad scope of the discussions.

The section on tuberculosis emphasizes eradication rather than control and indicates the value of mass x-ray-ing, but the value of examining the contacts of positive tuberculin reactors is

omitted. We in the West also feel that standards set for "approved milk" are not indicative of clean production methods and should not be exemplified.

The few minor criticisms which can be supported only serve to highlight the major importance of this excellent book.

WILTON L. HALVERSON

Functional Health Teaching Syllabus—By *Hynda M. Weber*. New York: Ginn, 1941. 165 pp. Price, \$1.75.

This report from the Committee on Functional Reorganization of Secondary School Curricula of the North Central Association of Colleges and Secondary Schools describes a 3 year experiment in teaching health to students in 8 high schools in Illinois and 1 in Wisconsin. It presents the kind of material that teachers of hygiene and health-minded science teachers are always looking for and never finding. For, after describing the objectives and procedures followed by the 9 schools in developing their *functional* health course, 9 teaching units are completely outlined. Each unit contains subject matter outlines for the teachers and a list of problems for students to solve.

The different informal methods used to evaluate the project will be of interest to the measurement-minded person. To the administrator and educator, however, the results agreed upon,

at a general conference held during the third year, will have greater significance. Representatives from the 9 schools subscribed to the following facts: That the functional health education classes were of more interest to students than regular biology or general science courses; that the influence of the functional emphasis had permeated the teaching of other classes; that coöperation had been promoted between the sciences, home economics, physical education, and medical work. Other recommendations favored making health training an all-school and a community project. Several schools had plans made for correlating health teaching with the social studies.

Faced with organizing a course such as this, certainly educators would agree neither on the main topics nor on the subject matter under each topic. This reviewer found herself reading the sections on posture and mental hygiene most critically. The fact remains, however, that here in print is a record of an experiment that puts into practice something health educators are always talking about but never quite succeeding in doing. Life problems are selected for study; the various sciences contribute the teaching of principles necessary to explain the problem; practising new knowledge in daily living builds up new values and habits.

DOROTHY B. NYSWANDER

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Fitter to Fight—This preview of the probable mortality statistics for 1941 is reassuring. Despite increasing birth rates, greater accidental and industrial death rates, there is promise of a 1941 mortality rate lower than in 1940. Few will question the heartening conclusion that we are entering this war in far better health than we did the last.

ANON. Mortality Record for 1941. Statistical Bull. (Metropolitan Life Ins. Co.) 23, 1:1 (Jan.), 1942.

Children Still Die from Diphtheria—Of the 93 cities represented in the annual compilation of needless diphtheria deaths, 40 had none. The rate for all, for the second time, is less than 1.0, and the actual number of deaths declined from 330 to 229. This is a remarkable record concludes the survey. But 229 are still 229 too many.

ANON. Diphtheria Mortality in Large Cities of the United States in 1940. J.A.M.A. 118, 9:714 (Feb. 28), 1942.

An Index of Obesity—Proposed here is a new classification of overweightedness on the basis of specific gravity. The procedure includes dunking the subject, tastefully attired in a lead belt. When the air is expelled from his lungs he is weighed while still under water. Then he is weighed on dry land. The two weights when used in a prescribed formula provide a really accurate measure of the body fat. The line dividing the pudgy from the scrawny is 1.060.

BEHNKE, A. R., JR., *et al.* The Specific Gravity of Healthy Men. J.A.M.A. 118, 7:495 (Feb. 14), 1942.

Respiratory Infections: Air Borne or Contact?—Little is definitely settled

about the manner in which respiratory infection viruses are spread, but the hypothesis that they are largely air-borne stands up better than the theory that they are spread chiefly by direct contact. The discussion of the three principal lines of research upon which this conclusion is based is long and involved but well worth your serious study.

BUCHBINDER, L. The Transmission of Certain Infections of Respiratory Origin. J.A.M.A. 118, 9:718 (Feb. 28), 1942.

The Eye in Public Health—Does the hygiene of the eye impinge ever so remotely upon your own little public health activity? Then you'll be interested in this series of six papers. Plato's quotation, "You can't cure the eye without healing the head, nor the head without healing the eye," sets the pace.

GALDSTON, I. The Society's Conference and What It Indicates for the Future (and five related papers). Sight-Saving Rev. 11, 4:251 (Dec.), 1941.

Just for the Record—Here is another study—by unimpeachable authority—indicating that the progress of caries in children can be substantially reduced by an intensive educational program in nutrition. Let's hope this matter remains settled, one way or the other.

HOWE, P. R. The Influence of Nutritional Supervision on Dental Caries. J. Am. Dental Assoc. 29, 1:38 (Jan.), 1942.

Industrial Hygiene and War Production—Despite all the fine scientific formulae, the work output of a human being is difficult to measure, and the problems of resulting fatigue are too subtle to yield to physiologic tests. But the experienced industrial hygienist

knows some rule of thumb combinations of rest, recreation, and good food that improve physical and mental fitness.

N.B. The lion's share of this issue is given over to formal papers and reports of discussions from the Fourth Annual Congress of Industrial Health. They are far too numerous to be listed separately here, but they are all of great moment to public hygienists. Hence you are adjured to seek them out and to digest them thoroughly.

Ivy, A. C. The Physiology of Work. J.A.M.A. 118, 8:569 (Feb. 21), 1942.

To End the Discussion—Claims that gelatin increases endurance are unfounded.

KING, E. Q., *et al.* Failure of Aminoacetic Acid to Increase the Work Capacity of Human Subjects. J.A.M.A. 118, 8:594 (Feb. 21), 1942.

Replacing the Village Health Board—Seventy per cent of us Americans are now living under some kind of a full-time local health administration. Defense areas are stimulating the creation of this essential service for some of the benighted 30 per cent. For a picture of the administrative set-up of our country see this report.

KRATZ, F. W. The Present Status of Full-time Local Health Administration. Pub. Health Rep. 57, 6:194 (Feb. 6), 1942.

Reassurance for Troubled Days—In Britain, war has accelerated the progress of the health services. Attention to nutrition and cessation of unemployment more than counterbalance the inevitable ill effects of war's preparations. Let us hope history repeats itself on this side of the water.

MAC GREGOR, A. The Public Health Services in the War. Pub. Health 55, 4:81 (Jan.), 1942.

Cancer's Habits—Skin cancer rates in three southern cities averaged 140; in three northern cities they were under 30. Most cases were among males and almost exclusively whites. There is much

more in this statistical study to provide a toothsome cud for mental rumination.

McDOWELL, A. J. The Incidence of Cancer in Dallas and Fort Worth, Tex., and Surrounding Counties, 1938. Pub. Health Rep. 57, 4:125 (Jan. 23), 1942.

It Can Happen Here, Too—Heartening indeed is this report upon the care of the numerous casualties from the attack upon Pearl Harbor. The operative experience upon the very large number of seriously wounded was far better than in the World War, chiefly because of the early care given, preliminary shock treatment, adequate debridement, and the use of sulfonamide drugs.

MOORHEAD, J. J. Surgical Experience at Pearl Harbor. J.A.M.A. 118, 9:712 (Feb. 28), 1942.

Public Health in War-time—Twenty top-notch articles on public health by a galaxy of the country's leaders—Armstrong, Boudreau, Cabot, Davis, Edie, Eliot, Emerson, Frant, Haggard, Heiser, Holland, Lindeman, McCloskey, Myerson, Parran, Perrott, Rice, Roberts, Snow, Whipple, Wile, and Winslow. It would be fruitless to attempt to comment on this excellent series here for you will want to preserve the whole collection in your reference files.

C.-E. A. WINSLOW, *et al.* Fitness for Freedom. Survey Graphic 31, 3 (Mar.), 1942. \$40 single copy, \$1.00 for four copies, \$.20 a copy in thousands.

Nutrition and Resistance to Infection—White mice on a diet deficient in riboflavin or thiamin were more susceptible to intranasal inoculation with pneumococci than were mice on an adequate diet, but the daily feeding of 5 to 10 times the amounts of these vitamins to the deficient animals after infection didn't do any good.

WOOLEY, J. G., and SEBRELL, W. H. Nutritional Deficiency and Infection. Pub. Health Rep. 57, 5:149 (Jan. 30), 1942.

ASSOCIATION NEWS

SEVENTY-FIRST ANNUAL MEETING

ST. LOUIS, MO., OCTOBER 27-30, 1942

Headquarters

MUNICIPAL AUDITORIUM

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- John A. Kahl, M.D., M.P.H., 636 South Palouse St., Walla Walla, Wash., City-County Health Officer
Elmer C. Kefauver, M.D., 209 East Second St., Frederick, Md., City-County Health Officer
James S. May, M.D., Allen Parish Health Unit, Oberlin, La., Director
William David May, M.D., Lauderdale County Health Dept., Meridian, Miss., Asst. Director
John G. Norris, M.D., 1112 Jackson St., Apt. 5, Monroe, La., Director, Caldwell Parish Health Unit
Joseph M. Silagy, M.D., 36 Eastway, Greenbelt, Md., Director of Public Health
Edgar W. Warren, M.D., 502 E. & Victor St., Abbeville, La., Director, Vermilion Parish Health Unit

Laboratory Section

- Edwin H. Albano, M.D., 144 Harrison St., East Orange, N. J., Director, Pathological Laboratories
Alexander I. Erasmus, 4238 Heather Rd. (Lakewood Village), Long Beach, Calif., Pharmacist's Mate, Medical Dept., U. S. Navy
Mattie Pearl Henderson, M.S., 309 Market St., Knoxville, Tenn., Acting Director, City and State Branch Laboratory
Frank L. Horsfall, Jr., M.D., C.M., E. 66th St. & York Ave., Rockefeller Institute, New York, N. Y., The Hospital of the Rockefeller Institute for Medical Research
John A. Layne, M.D., 410 Central Ave., Great Falls, Mont., Division of Medicine, Great Falls Clinic

- Frank E. Lescanec, B.A., Clarke-Wayne County Health Dept., Shubuta, Miss., Sanitation Supervisor
Milton L. Lewis, M.S., P. O. Box 235, U. S. Submarine Base, Coco Solo, Canal Zone, Bacteriologist, U. S. Navy
Martha E. McGilvray, Dixon State Hospital, Dixon, Ill., Junior Bacteriologist, State Dept. of Public Welfare
Ruth E. Miller, Ph.D., Woman's Medical College of Pennsylvania, Philadelphia, Pa., Bacteriologist
John A. Pence, B.S., Sanitary Milk Co., Rantoul, Ill., Dairy Bacteriologist

Vital Statistics Section

- Bernard D. Karpinos, Ph.D., National Institute of Health, Bethesda, Md., Assoc. Economist
Blanche C. Knight, B.A., City Hall Annex, Berkeley, Calif., Statistician, Berkeley Health Dept.
Ben H. Sklar, M.S.P.H., 603 Fountain St., Ann Arbor, Mich., Statistician, Michigan Dept. of Health, Bureau of Epidemiology

Engineering Section

- Selwyn T. Chalker, Jr., B.S., P. O. Box 75, Hinesville, Ga., Sanitarian, Liberty County Health Dept.
J. Frank Field, B.S., 203 Golf Club Lane, Nashville, Tenn., Chief Sanitary Engineer, State Dept. of Public Health
George F. McKenzie, Mason County Health Dept., Maysville, Ky., Sanitary Inspector
Fred L. Moesel, Sanitary and Water Supply Engineer, Princeton Junction, N. J.
Howard E. Munro, Bahamas General Hos-

pital, Nassau, Bahamas, Sanitary Inspector,
Public Health Dept.
Laban M. Poston, City Hall, Borger, Tex.,
City Inspector, City Health Dept.
Reeve Lee Sensabaugh, B.S., City Hall, Mus-
kegon, Mich., Supt. of Water Supply, City
of Muskegon

Industrial Hygiene Section

Thomas H. Cooper, B.S., 2220 Birch St.,
Denver, Colo., Industrial Hygiene Engineer,
State Board of Health
Albert E. Heustis, Jr., M.D., 116 Oaklee Vil-
lage, Baltimore, Md., Student, Johns
Hopkins Univ.
Adolph G. Kammer, M.D., 3210 Watling St.,
East Chicago, Ind., Medical Director, Inland
Steel Company
Milton Sheinbaum, B.Ch.E., 4408 Butterworth
Place, Washington, D. C., Junior Public
Health Engineer

Food and Nutrition Section

Bert W. Bierer, V.M.D., Joppa Rd. & Clement
Ave., Towson, Md., Veterinary Inspector,
Baltimore City Health Dept.
Milton P. Duffy, 612 Phelan Bldg., San Fran-
cisco, Calif., Chief, Bureau of Food and
Drug Inspection, State Dept. of Public
Health
Julia C. Dwight, M.S., 262 Madison Ave.,
New York, N. Y., Nutrition Consultant,
Henry Street Visiting Nurse Service

Maternal and Child Health Section

Francis I. Livingston, D.D.S., M.S.P.H., Smith
Tower, Seattle, Wash., Dental Consultant,
Maternal and Child Health Division, State
Dept. of Health

Public Health Education Section

Harold D. Cramer, M.D., Student Health
Service, Univ. of Idaho, Moscow, Ida.,
Director
Alan L. Hart, M.D., P. O. Box 1703, Boise,
Ida., Tuberculosis Consultant, Idaho Tuber-
culosis Assn., and State Dept. of Health
L. W. Hutchins, 420 Lexington Ave., New
York, N. Y., Managing Director, Safety
Research Institute
Edith M. Lindsay, M.A., Mills College, Oak-
land, Calif., Hygiene Teacher
Robert C. Miller, Ph.D., Calif. Academy of
Sciences, San Francisco, Calif., Museum
Director
John R. Nichols, Ph.D., Univ. of Idaho,
Pocatello, Ida., Executive Dean
Claude C. Pierce, M.D., Sub-Treasury Bldg.,

15 Pine St., New York, N. Y., Director,
U. S. Public Health Service District 1
Stella Randolph, M.A., 5848 University Ave.,
Chicago, Ill., Student, Chicago University
Ethel L. Sherman, R.N., Crowley County
Public Health Nurse, Ordway, Colo.
Joseph L. Stenck, 128 W. 74th St., New York,
N. Y., Asst. Director, in Charge of Publicity,
American Social Hygiene Assn.
Dr. Miguel Veve, Yabucoa, Puerto Rico,
Clinic Physician
Marian D. Williamson, R.N., 301 Heyburn
Bldg., Louisville, Ky., Director, The Ken-
tucky Crippled Children Commission

Public Health Nursing Section

M. Patience Carr, R.N., M.A., State Dept.
of Health, Trenton, N. J., Public Health
Nurse, U. S. Public Health Service
A. Frances George, R.N., B.S., 712-6th Ave.,
Lewiston, Ida., Public Health Nurse, North
Central Idaho Health Unit
Laura S. Justice, R.N., County Public Health
Nurse, P. O. Box 115, Berkeley Springs,
W. Va.
Helen J. Marble, 4 Baptist St., Pawtucket,
R. I., Director of Nurses, Visiting Nurse
Assn.
Rose C. McKeon, R.N., 1001 W. 46th St.,
Miami Beach, Fla., Public Health School
Nurse
Ethel M. Russell, 1933 Crafton Blvd., Craf-
ton, Pa., Supervisor of Public Health Nurses,
Pittsburgh Public Health Nurses Assn.
Vilma Schuster, B.S., 909 North Missouri,
Roswell, N. M., Regional Public Health
Nursing Consultant, State Dept. of Public
Health
Miriam E. Scofield, R.N., 53 Weed Ave.,
Stamford, Conn., Staff Nurse, Visiting
Nurse Assn.
Josephine D. Talbott, R.N., B.S., 619 Clinch
St., Knoxville, Tenn., Supervising Nurse,
Venereal Div., Bureau of Health
Marjorie Tucker, B.N., 60 Guernsey St., Stam-
ford, Conn., Executive Director, Stamford
Visiting Nurse Assn.
Alberta B. Wilson, R.N., C.P.H., 8 The
Green, Dover, Dela., Director of Public
Health Nursing, State Board of Health

Epidemiology Section

Ludwik Anigstein, M.D., Ph.D., School of
Medicine, Univ. of Texas, Galveston, Tex.,
Assoc. in Preventive Medicine and Public
Health
William I. Fishbein, M.D., 54 W. Hubbard
St., Chicago, Ill., Epidemiologist, Chicago
Dept. of Health

Charles J. Grubin, M.D., 6409 3rd St., Washington, D. C., Asst. Surgeon (Reserve), U. S. Public Health Service

Philip H. Narodick, M.D., 307 Cobb Bldg., Seattle, Wash., Supt. and Medical Director, King Co. Tuberculosis Hospital

Dr. Francisco Ruiz-Sanchez, Hidalgo 73 Pte., Culiacan, Sinaloa, Mexico, Chief Epidemiologist, Sanitary Service

Thamara M. Stander, M.D., M.S.P.H., 28 Belmont Parkway, Hempstead, N. Y., Junior Epidemiologist, Nassau County Dept. of Health

Unaffiliated

Melbourne Murphy, M.S.P.H., 1022 Granger, Ann Arbor, Mich., House Manager, University Health Service

Simon Noc Jaime, M.D., Rosales 20-206, Mexico, D. F., Mexico, Student, National University of Mexico

Martha M. Penfield, 156 Maple Street, Englewood, N. J., Interested Citizen

DECEASED MEMBERS

Mrs. Catherine R. Atley, Boise, Ida., Elected Member 1920—Unaffiliated

Thomas F. Birmingham, M.D., Galesburg, Ill., Elected Member 1937, Health Officers Section

Henry C. Brown, M.D., San Jose, Calif., Elected Member 1923, Health Officers Section

Ruth L. Conrad, Altadena, Calif., Elected Member 1935, Public Health Education Section

George Fordham, M.D., C.P.H., Powellton, W. Va., Elected Member 1926, Elected Fellow 1930, Industrial Hygiene Section

Carlos Manuel Garcia, M.D., Habana, Cuba, Elected Member 1936, Laboratory Section

Merrill J. Mack, Amherst, Mass., Elected Member 1928, Elected Fellow 1933, Food and Nutrition Section

Felix Seligman, Duluth, Minn., Elected Member, 1934, Engineering Section

Mary B. Willeford, Ph.D., R.N., Washington, D. C., Elected Member 1939, Public Health Nursing Section

AMERICAN MUSEUM OF HEALTH

THREE new members join the Board of Directors of the American Museum of Health for its first regular meeting in 1942 on April 27. The new Directors, elected at the Fifth Annual Meeting of the Museum in January are: John A. Marcuse, Basil O'Connor, and Edwin A. Salmon. Mr. O'Connor was elected Treasurer of the Museum.

The annual report of George McAneny, President, and Dr. Louis I. Dublin, Chairman of the Board, indicated that negotiations were proceeding toward the establishment of the Museum in a wing of the American Museum of Natural History. Preliminary studies for the necessary construction work entailed in this move have been authorized by the City Planning Commission, according to Commissioner Salmon, and James A. Dawson, representative of Commissioner of Parks Moses on the Museum's Board.

Over 300,000 people have seen the Museum's exhibits since the close of the Fair, according to the report of

Homer N. Calver, Secretary. Through its exhibit loan program Museum materials were displayed by 14 organizations in 12 cities during the past year. He also announced the forthcoming publication of the first report on the Visitor Reaction Study, conducted by the Museum and the U. S. Public Health Service, under a grant from the Carnegie Corporation of New York. The report, *What the Public Knows About Health*, comprises a compilation of the results of the Health Knowledge Tests given at the New York World's Fair and the San Francisco Golden Gate Exposition.

TWO NEW A.P.H.A. SECTION SECRETARIES

THE Vital Statistics Section Council has elected Hugo Muench, Jr., M.D., to serve as the Acting Secretary of the Section to replace John Collinson, M.D., who has resigned.

The Public Health Education Section Council has elected W. W. Bauer, M.D., Acting Secretary of the Section to replace Hugh R. Leavell, M.D., who has resigned.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y.

U. S. CIVIL SERVICE COMMISSION

The Commission has announced that applications will be received for positions as Senior Medical Officer (\$4,600), Medical Officer (\$3,800), and Associate Medical Officer (\$3,200) for appointments in the Public Health Service, with the Food and Drug Administration, Veterans' Administration, and the Indian Service. Forms for application may be obtained from the U. S. Civil Service Commission, Washington.

The Commission has announced unassembled examinations for Junior Public Health Nurse at \$1,800 a year and Junior Graduate Nurses at \$1,620 a year, under which the training and age requirements of announcements No. 88 and 103 of 1941 have been amended. Persons interested should communicate with the U. S. Civil Service Commission in Washington or obtain the amended announcements at any first or second class post office.

The Commission announces unassembled examinations for Home Economists in 5 different grades at \$2,600 to \$5,600 a year. Interested persons should apply to the Commission for Circular 195 on Home Economics.

PHYSICIANS NEEDED IN CANAL ZONE

The U. S. Civil Service Commission announces an examination to secure physicians for clinical service in the Panama Canal Zone. Graduation from a class A medical school subsequent to May 1, 1920, is required, and the applicant must be under 50, 25 to 35 years of age preferred. Entrance salary \$4,000. Persons interested should communicate with the U. S. Civil Service Commission, Washington.

WYOMING MERIT SYSTEM COUNCIL

The Wyoming Merit System Council announces unassembled examinations for positions in the field of Maternal and Child Health, Dental Hygiene, Health Education, Public Health Nursing, Physical Therapy, Medical Social Work, Public Health Engineering, Epidemiology, County Health Administration, Vital Statistics, and Public Health Laboratory. Also written examinations in Public Health Nursing, 5 grades, Sanitarian and Laboratory Technician, 2 grades.

It is expected that applications can be filed until April 18. Copies of announcement and application forms may be secured from the Wyoming Merit Supervisor at Newcastle, Wyo. Wyoming residence waived.

POSITIONS AVAILABLE

Western state department of health will consider applications from physicians to fill four existing vacancies among county health officers, one vacancy in venereal disease control and positions as laboratory technicians. Write Box S, Employment Service, A.P.H.A.

County Public Health Nurses for New Mexico. Must have four months' post-graduate instruction under one of the recognized public health nursing courses and one year's experience. Must drive and have a car. Address inquiry to State Health Department, Santa Fe, N. M.

Physician with either public health training or experience in local health de-

partment administration to serve as health director in a county health department in mid-western state. Salary \$4,000 and \$500 travel (flat rate). Well established department with offices in attractive little city of 10,000. Write Box T, Employment Service, A.P.H.A.

Wanted: Trained Public Health Nurse, starting salary \$1,500 per year and traveling expense, increase to \$1,620 within 6 months. Saginaw County Health Dept., Saginaw, Mich.

The State Department of Social Security and Welfare, Crippled Children's Division, of Phoenix, Ariz., has three vacancies to be filled. Examinations will

soon be held for orthopedic nursing consultant, nurse-physical therapist, and medical social worker.

Further information may be obtained by writing to the Merit System Supervisor, Room 208, 128 North First Avenue, Phoenix, Ariz.

The New Mexico State Department of Health will consider applications for position of Obstetrical Consultant for Demonstration Unit in Maternal and Child Health. Address inquiries to State Department of Public Health, Santa Fe, New Mexico.

The New Mexico State Department of Health will consider applications for the position of Nutrition Consultant. Address inquiries to State Dept. of Public Health, Santa Fe, New Mexico.

PUBLIC HEALTH ENGINEER

Responsible professional public health engineering involving field investigations and office studies in the application of sanitary measures. The more difficult engineering and sanitation field surveys include supervision over public water supplies, sewerage systems and sewage treatment plants and review of plans for same, and promotion and supervision of sanitation programs. Minimum qualifications: Training and experience equivalent to 3 years' civil engineering experience, including 2 years in public health or sanitary engineering; *or* completion of an academic year of graduate study and a year's experience in sanitary or public health engineering; *and* graduation from a college of recognized standing with a major course in civil or sanitary engineering. The salary range is \$205 to \$250 per month depending upon experience. Apply Box E, Employment Service, A.P.H.A.

OTHER VACANCIES

Southwestern State Health Department seeks 2 physicians for assignment to district health units, personally to conduct several small venereal disease clinics on

a rotating schedule. Experience preferred but not required. Salary \$3,000, plus actual travel allowance not to exceed \$1,200. Write Box V, Employment Service, A.P.H.A.

Middle western city, 125,000 population, seeks well trained and experienced Health Officer on full-time, with competence to administer a department and teach public health to medical students. Salary \$5,000 to \$5,500 per annum. Write Box K, Employment Service, A.P.H.A.

The New Mexico State Department of Public Health will consider applications for the position of Assistant Director of the Maternal and Child Health Division and for Dental Health Consultant of that Division. Address inquiries to the State Department of Public Health, Santa Fe, N. M.

Bacteriologist, M.S. or Ph.D., with 3-5 years' applied experience in the field of sanitation and disinfection wanted by prominent eastern manufacturer for research and development work. Creative ability must be established. Consideration will be given only to those who fully meet the above requirements. In replying give full academic record, scientific and personal references, and recent photograph will be requested. Write Box P, Employment Service, A.P.H.A.

Wanted: Trained Public Health Nurse, starting salary \$1,500 per year and traveling expenses. Increase may be expected within 6 months. Shiawassee County Health Department, Corunna, Mich.

Wanted: Nurse for county health work. Salary \$1,800 per year with travel allowance (additional) of \$500 per year. Address District Health Department 2, West Branch, Mich.

Instructor in Bacteriology, Medical School, large midwestern university, M.D. (or Ph.D. or D.Sc. in Bacteriology); Male. Salary \$1,800 to \$2,500 according to age and experience. Write Box D, Employment Service, A.P.H.A.

POSITIONS WANTED

ADMINISTRATIVE

Teaching or administrative position desired by physician, aged 48. Experienced teacher in preventive medicine and public health, now employed at prominent medical school; 20 years' experience in municipal health administration and epidemiology. A-491

Physician, B.S., M.D., and M.S.P.H., University of Michigan, aged 35, experienced city-county health administration and as director university student health service. Will consider permanent responsible position offering good income. A-492

Physician, age 32, 5 years' clinical and administrative experience in venereal dis-

cases, wishes administrative position in venereal disease control, preferably at state level. A-490

HEALTH EDUCATION

Teacher and research worker, man, Ph.D., age 52. Extensive record as college professor of biology and hygiene and investigator; for the past two years engaged in research. H-499

Health Educator, Negro, man with background of High School administration and M.S.P.H. from University of Michigan, seeks position in Health Education. Public agency or educational field. Excellent references. H-497

Woman, M.S. in public health, excellent graduate training in education, 8 years' experience as business executive (sales and publicity). Just completed year's research in community education. Seeks good administrative position. H-496

Health Educator, M.A. in Education, 10 years' background in community organization for public health education, also teaching of personal and community health at high school and college levels. Public health nurse, able to teach mental and social hygiene as well as general health education. East preferred. H-498

Health Educator. Man with M.S. in preventive medicine and public health. Negro. Seeks position in Health Education or field work with official or non-official agency. H-500

Woman with master's degree in health education, 12 years' successful experience in public school and college teaching, administration and research. Will consider position in normal school, public schools, or in official or nonofficial health agencies. Prefers South or East. Available at once. H-501

LABORATORY

Milk Sanitarian and Technologist, age 37, Ph.D., Bacteriology, Wisconsin; 10 years' experience in milk and food sanitation from industrial and official angle, seeks administrative position with opportunity for research or investigational work preferred. L-381

Chemist, Sc.D., Biochemistry, Johns Hopkins University. Age 31. Public health laboratory experience, teaching experience. Desires position with promise of advancement, preferably in commercial organization. L-461

Bacteriologist, young man 28, with B.S. in industrial science, experienced in newspaper work, salesmanship and now employed in state department of health laboratory, seeks position as bacteriologist or doing promotional work of public health nature. L-465

SANITARY ENGINEERING

Public Health Engineer, M.S. Harvard, experienced in public health and industrial hygiene, wishes position of better sort in public health engineering or industrial hygiene. E-470

STATISTICAL

Woman with academic, business and research experience in vital statistics, seeks a position in the vital statistics division of a state or city health department, preferably as registrar. S-459

Experienced and well trained public health nurse, with background of tuberculosis, venereal disease, school, industrial, and generalized services, will shortly be available for appointment. Three years as director of state nursing service. Experienced as university teacher of public health nursing. M.A., New York University. M-449

Opportunities Available

PUBLIC HEALTH PHYSICIANS—(a) Pediatric consultant; state health department; 2 to 3 years' training in pediatrics required; \$3,900-\$4,800; Midwest. (b) Medical director, western rural area; emphasis on maternal and child health; must be qualified to exercise leadership in organization and administration of medical services. (c) Venereal disease clinician qualified to direct several small clinics; appointment newly created; around \$4,200; South. PH4-1, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

PUBLIC HEALTH NURSES—(a) Director of nurses for municipal public health nursing service; Gulf state. (b) Educational director; well known maternity service; degree, year's course public health nursing required; obstetrical experience desirable; \$200. (c) Out-patient department supervisor qualified to combine duties with those of instructor of public health nursing; clinic con-

nected with splendid 200 bed hospital; minimum entrance stipend, \$140, meals; early increase. (d) Orthopedic field nurse, state health department; duties include direction of services to crippled children in all areas not organized in health units; public health certificate, postgraduate work orthopedics required; \$165, travel allowance. (e) Graduate nurse with some formal training in public health for appointment as public health nurse on staff of children's hospital (universally affiliated); knowledge of nursing education essential; \$125, mileage allowance. PH4-2, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

LABORATORY DIRECTOR—Man or woman with Ph.D. or M.D. degree, thoroughly qualified in bacteriology and serology for appointment as director of state-registered laboratory; around \$200; Midwest. PH4-3, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

Advertisement

Situations Wanted

PUBLIC HEALTH PHYSICIAN—Certified public health physician is available; bachelor's and medical degrees from southern university; C.P.H., Johns Hopkins; 4 years, director student health service, state university; 5 years, executive position with state health department. PH4-4, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

BACTERIOLOGIST AND IMMUNOLOGIST—Ten years' teaching and research in immunology, leading university; B.S., Ph.D. degrees; memberships: American Association Pathologists and Bacteriologists, American Association of Immunologists.

PH4-5, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

PUBLIC HEALTH NURSE—Excellent trained public health nurse is available; A.B. degree, eastern college; graduate of school of nursing of university hospital; year's postgraduate training public health nursing; certified; nearly 15 years' executive experience in public health nursing; past several years, executive secretary, city health council; a very superior woman of broad and varied experience; has made distinct contribution to field of public health nursing. PH4-6, Medical Bureau (Burneice Larson, Director) Palmolive Building, Chicago.

NEWS FROM THE FIELD

COMMISSION ON CHILDREN IN WARTIME

THE Children's Bureau Commission on Children in Wartime, including 56 members appointed by Katharine F. Lenroot, Chief of the Children's Bureau of the U. S. Department of Labor, ended its three day session in Washington, D. C., on March 18, with the adoption of a Children's Charter in Wartime. The charter reads in part—

We call upon citizens young and old to join together to:

I. Guard children from injury in danger zones.

II. Protect children from neglect, exploitation, and undue strain in defense areas.

III. Strengthen the home life of children whose parents are mobilized for war or war production.

IV. Conserve, equip, and free children of every race and creed to take their part in democracy.

Concrete recommendations for translating these principles into action were adopted. They are summarized below. The paragraph numbers correspond to the number of the objective.

I. The registration and identification of all children; the evacuation of children with their mothers, if possible, from danger zones with plans for adequate reception and care; the expanding of summer vacation camps for city children using volunteers, surplus commodities, and other aids as tests of evacuation methods and as an investment in health; appropriate immunization of all children against communicable disease; attention to the alleviation of childhood anxiety.

II. The maintenance of adequate health and welfare services for children

and their parents in every community where war production or military camps are located; the assignment of obstetricians and pediatricians to defense areas; the establishment of child guidance clinics; the expansion of school opportunities, including nursery schools for young children; the placement of recreation leaders, group workers, and child welfare workers in defense communities where facilities for play and for recreation centers are overtaxed.

III. By providing for the economic needs of children whose fathers are in the Service and for medical and hospital care for wives and children; supplementing the Social Security program with a government insurance program for civilians injured or killed as a result of war activities; providing adequate housing, with health services and group activities for children in all housing projects; assisting mothers who are employed, or planning to enter employment, with care of children, including health supervision, opportunity for nursing, recreation outside school hours; extending government aid to dependent children of all parents economically unable to maintain a home for their children; providing general assistance and benefits for temporary and permanent disability.

IV. By providing public health nursing service, prenatal clinics, delivery care, child health conferences and clinic and hospital service for sick children in every county in the United States; providing school meals and extending penny milk to all children; expanding social

services for children; providing leisure time activities; analyzing demands for the employment of children to determine whether all available adult man power has been utilized and distinguishing between labor shortage and the desire to obtain cheap labor; discouragement of employment of children at wages that undermine wages for adult labor, of children under 14, of children under 16 in manufacturing and mining occupations, of children under 18 in hazardous occupations; providing a nation-wide extension of health services for school children, including medical care as needed and health instruction, with the coöperation of health and education authorities; encouragement of boys and girls to participate in home and community war efforts.

The commission adopted three resolutions on maternal and child health services, on child welfare services, and on increasing federal appropriations for health and welfare services for maternity patients and children in defense areas.

Dr. Leonard Mayo, Dean of the School of Applied Social Services, Western Reserve University, Cleveland, Ohio, and President, Child Welfare League of America, was elected Chairman of the commission and was authorized to appoint an executive committee to carry on the work of the Commission between meetings. The executive committee as appointed includes:

Leonard Mayo, Cleveland, Ohio, *Chairman*
 Edith Abbott, Chicago, Ill.
 Fred L. Adair, M.D., Chicago, Ill.
 Mildred Arnold, Indianapolis, Ind.
 M. O. Bousfield, M.D., Chicago, Ill.
 Robin C. Buerki, M.D., Philadelphia, Pa.
 Charlotte Carr, Chicago, Ill.
 Horton Casparis, M.D., Nashville, Tenn.
 Grace L. Coyle, Cleveland, Ohio
 Henry F. Helmholz, M.D., Rochester, Minn.
 Ellen C. Potter, M.D., Trenton, N. J.
 George S. Stevenson, M.D., New York, N. Y.
 Katharine Tucker, Philadelphia, Pa.
 Herbert D. Williams, Warwick, N. Y.

Other members of the commission from the field of public health included:

Reginald M. Atwater, M.D., New York, N. Y.
 Leona Baumgartner, M.D., New York, N. Y.
 Courteney Dinwiddie, New York, N. Y.
 Homer Folks, New York, N. Y.
 Percy F. Guy, M.D., Seattle, Wash.
 Ruth Houlton, New York, N. Y.
 Felix J. Underwood, M.D., Jackson, Miss.

INTERPRETING THE TIRE RATIONING REGULATIONS FOR THE PUBLIC HEALTH WORKER

REPLYING to a recent inquiry from the American Public Health Association as to the application of the Tire Rationing Program to public health departments and their employees, the following statements have been made on behalf of J. K. Galbraith and the Rubber and Rubber Products Section of the Office of Price Administration, Washington:

Under the Regulations vehicles which are used exclusively in the enforcement of laws which relate specifically to the protection of public health and safety are eligible for tires. The law enforcement services must relate directly to the protection of the public from accident and disease. Vehicles which are eligible under this section cannot be used to convey public health and safety officials to and from their usual stations, except in case of emergency. The Local Boards are not authorized to issue certificates to public health officials where public means of transportation will serve.

A vehicle used exclusively by a visiting nurse for professional services is also eligible for tires. A visiting nurse has been defined as any nurse who is employed by a clinic, hospital, government agency and similar organizations, or by an industrial concern to make nursing or inspection calls for such agencies. The term visiting nurse does not include private nurses.

All applications for tire certificates must be made to Local Tire Rationing Boards.

NUTRITION FOUNDATION INCORPORATED

IT was announced on March 13 that the Nutrition Foundation, Inc., New York, N. Y., recently formed by a group

of food industries "to develop and apply the science of nutrition for the improvement of the diet and health of the American people," would have as its scientific director Professor Charles G. King, F.A.P.H.A., of the University of Pittsburgh, a nutrition authority. Professor King has been associated with Washington State College, the University of Pittsburgh, Columbia University, the Johns Hopkins University, and the University of Cambridge, England. In 1932 he isolated vitamin C, a work carried out independently but simultaneously with the isolation of the same vitamin for which Dr. Szent Gyorgyi of Budapest was awarded the Nobel Prize. Professor King received the award of the Pennsylvania Public Health Association in 1939 and the Nutrition Award in 1941 in recognition of his scientific contributions to this field.

President Karl T. Compton of the Massachusetts Institute of Technology, Chairman of the Foundation's Board of Directors, announced that George A. Sloan, Commissioner of Commerce of New York City, would be President of the Foundation. Mr. Sloan revealed that 16 food companies have so far subscribed \$800,000 to the new foundation, which has now completed its organization.

Dr. Compton said that "the problem of nutrition will become increasingly a desperate world problem as the war proceeds and will be one of the greatest of all world problems in the period of reconstruction which will follow. The objective of the Nutrition Foundation is to aid in the discovery of scientific facts regarding nutrition and to aid in making these facts available to the public which eats food, in such a manner that the diet of the American people may be improved as much as possible in the directions indicated by soundly established scientific findings."

Professor King said that "the primary

emphasis in the Foundation's program shall be upon service to humanity expressed through the medium of research in nutrition." Federal Security Administrator, Paul V. McNutt, told the nutritionists and food industrialists that there were two problems upon which emphasis must be placed—"that of translating science into action, and that of solving the problem of reaching the ultimate consumer." The consumer, he said, must be reached with the facts and those facts must carry a conviction that will lead to action. Means must be found to gear the manufacturer, the advertiser, and the grocer into the one great objective of getting better food to every family's dinner table.

U. S. PUBLIC HEALTH SERVICE ORIENTATION COURSE FOR PUBLIC HEALTH PERSONNEL

AN orientation course for medical officers, public health nurses, sanitary engineers, and laboratory technicians organized under the auspices of the U. S. Public Health Service at the National Institute of Health, Bethesda, Md., and in coöperation with nearby public health agencies, has been offered from April through December, 1942.

Four hundred and sixty-eight public health workers have received special instruction to fit them for duty in emergency health and sanitation work in defense areas. Of the total, 100 were medical officers, 127 nurses, and 241 sanitary engineers and laboratory technicians, all of whom have now been assigned to the eight districts of the Public Health Service and among 46 states and territories.

In reporting the completion of this work, Senior Surgeon M. V. Ziegler, M.D., as Director, has described the curriculum offered to these individuals and the methods which have been used to prepare qualified persons in response to the urgent demands for additional

public health personnel from the states and territories. Assisting Dr. Ziegler have been Anna Heisler, Associate Director of Nursing, as nursing consultant, and Sanitary Engineer E. S. Tisdale, Associate Director of Engineering. Three divisions of the Public Health Service, namely, Personnel and Accounts Division, States Relations Division, and the National Institute of Health have had the major responsibility of carrying out the orientation courses.

EMERGENCY CASUALTY HOSPITAL PLANS

PAUL V. McNUTT, Federal Security Administrator, and **James M. Landis**, Director of the Office of Civilian Defense, Washington, announced on March 12 the plan to provide temporary hospitalization for civilians injured as the result of enemy action.

This program will be carried out by the Medical Division of the OCD in coöperation with the U. S. Public Health Service and state and local authorities. It provides that all voluntary and governmental hospitals in the nation may serve as Casualty Receiving Hospitals of the Emergency Medical Service. Hospitals so engaged will be reimbursed by the federal government for the care of such casualties at established rates. Certain hospitals and other institutions in safe areas are to be designated as Emergency Base Hospitals for reception of casualties or other patients whom it may be necessary to evacuate from Casualty Receiving Hospitals.

NEW DIVISION IN OFFICE OF INTER-AMERICAN AFFAIRS

THE Coördinator of Inter-American Affairs, **Nelson A. Rockefeller**, on March 5 announced a program aiming to promote the health and defense of the Western Hemisphere. It will be directed by **Dr. George C. Dunham**, formerly of the Army Medical Corps, as head of a division of health and

sanitation in the Office of Inter-American Affairs.

According to the press, this mission will carry out recommendations of the Inter-American Conference at Rio de Janeiro and will concentrate on those areas which are considered vital in carrying out the defense of the hemisphere. Among other projects will be the regulation of water supplies, waste disposal systems, building of hospitals in defense areas, and the training of health and sanitation specialists in the Latin American countries.

It is stated that this program will be linked with activities of the Pan American Sanitary Bureau, as well as with the commissions organized in the other American republics under the Inter-American Development Commission and various private foundations. Work is already under way near Quito and Guayaquil in Ecuador. **Dr. Walter C. Earle** and **Wyman Stone**, sanitary engineers, are also identified with the division.

ECUADOR INSTITUTE OF HYGIENE

A NATIONAL Institute of Hygiene has been created at Guayaquil, Ecuador; it will be housed in a new building now under construction. The International Health Division of the Rockefeller Foundation, New York, and the government of Ecuador are financing the project, as well as sharing the maintenance for a five year period, after which time it is expected that the Ecuadorian government will assume complete responsibility. There will be installed in the new building the laboratories of bacteriology, chemistry, medical research, preparation of anti-smallpox vaccine, bacterial vaccines, anatoxins, BCG laboratory, special laboratories for epidemics and yellow fever, and in future the preparation of therapeutic sera. It is also planned to have departments for general services to the public.

MINIMUM REQUIREMENTS FOR PLUMBING AND STANDARDIZATION OF PLUMBING EQUIPMENT

AN important Sectional Committee of the American Standards Association on Minimum Requirements for Plumbing and Standardization of Plumbing Equipment (A40) was organized in 1928 under the sponsorship of the American Society of Mechanical Engineers. The scope of this sectional committee includes minimum requirements for plumbing, including water supply distributing systems, drainage and venting systems, plumbing fixtures, apparatus devices; and the standardization of plumbing equipment, including materials, uniformity of roughing-in dimensions, efficiency of operation, and other performance specifications.

In accordance with American Standards Association procedure, this committee has been set up with representation from industry, from government, from the public, and from several specialties, including architects, hospital administrators, ceramic experts, hotel officers, real estate operators, marine engineers, and others.

Among several subcommittees, Subcommittee No. 1 on Minimum Requirements for Plumbing is most closely related to public health. Theodore I. Coe of the American Institute of Architects, Washington, D. C., is Chairman.

At the suggestion of the sponsor, an invitation has been extended by the American Standards Association Council to the American Public Health Association to be represented on Committee A40 and Subcommittee No. 1 with two delegates and, in addition, to become co-sponsor of the committee with the American Society of Mechanical Engineers. This invitation has been accepted. The Association is now a co-sponsor, and Dr. Abel Wolman, Chairman of the Executive Board of the Association, has designated as the A.P.H.A. representatives to Committee

A40 and to Subcommittee No. 1 Sol Pincus, Deputy Commissioner of Health, New York City Department of Health, and M. Warren Cowles of the Hackensack Water Company, New Milford, N. J.

Among other members of this committee and subcommittee the following from the field of public health are noted: Dean Thorndike Saville, Professor Charles G. Hyde, Professor F. M. Dawson, Major Joel I. Connolly, Charles A. Holmquist, Arthur P. Miller, and James F. Murphy.

WESTERN BRANCH A.P.H.A. MEETS IN SEATTLE MAY 27-29

DR. ADOLPH WEINZIRL, Portland, Chairman of the Program Committee of the Western Branch of the American Public Health Association has announced that the meetings in Seattle, May 27 to 29, will be centered around the theme, "Health Services in War Time." Dr. Weinzirl and his committee are formulating the program with a focus on the health and protection services that are most affected by the war situation. The medical protection of civilians in disaster, the shifting of population groups due to the war effort, and new health implications, accentuated hazards, changes in emphasis and administrative problems will be considered.

CONSERVATION OF SCHOLARLY JOURNALS

THE American Library Association created in 1941 the Committee on Aid to Libraries in War Areas, headed by John R. Russell, the Librarian of the University of Rochester. The committee is faced with numerous serious problems and hopes that American scholars and scientists will be of considerable aid in the solution of one of these problems.

Many sets of journals will be broken by the financial inability of the institutions to renew subscriptions. As far as possible they will be completed from a stock of periodicals being purchased by the committee. Many more will have

been broken through mail difficulties and loss of shipments, while still other sets will have disappeared in the destruction of libraries. The size of the eventual demand is impossible to estimate, but requests received by the committee already give evidence that it will be enormous.

With an imminent paper shortage attempts are being made to collect old periodicals for pulp. Fearing this possible reduction in the already limited supply of scholarly and scientific journals, the committee hopes to enlist the coöperation of subscribers to this journal in preventing the sacrifice of this type of material to the pulp demand. It is scarcely necessary to mention the appreciation of foreign institutions and scholars for this activity.

Questions concerning the project or concerning the value of particular periodicals to the project should be directed to Wayne M. Hartwell, Executive Assistant to the Committee on Aid to Libraries in War Areas, Rush Rhees Library, University of Rochester, Rochester, N. Y.

FURTHER RESTRICTIONS ON THE USE OF CHLORINE

THE Division of Industry Operations, War Production Board, Washington, on February 27 released an order, WPB 362, covering drastic restrictions on the use of chlorine.

A-2 ratings are given to chlorine for the treatment of potable water and for sewage treatment. A-6 ratings are given to hospital uses, dairy and other food processing plant sanitation, public eating and drinking establishment sanitation, public and institutional swimming pool sanitation, and for the manufacture of products for medicinal, surgical, dental and veterinarian uses. Private swimming pools are classified as B-5.

Interpreting this order, W. H. Chamberlain, the Chief of the Chlorine Unit,

states under date of March 7 that the Chlorine Unit interprets public and institutional pools as those used by the public and open to anyone, either free or on the basis of a fee. Private pools are those whose use is restricted to members only, or for home use.

The A.P.H.A. has been requested to advise persons concerned with the use of chlorine that it is necessary to return empty cylinders to the supplier as promptly as used.

This order, WPB 362, prohibits the use of chlorine or products containing available chlorine in the bleaching of foodstuffs, the bleaching of wiping rags and waste, and the manufacture of cosmetics and toilet preparations. Curtailments are applied to laundry operations, private swimming pools and in certain other activities. No further restrictions are made on pulp and paper manufacturers. It is believed that sufficient chlorine will be available to fill at least some of the demands for all the ratings, although chlorine is in demand for a variety of war uses.

TWELFTH NEW ENGLAND HEALTH INSTITUTE

THE Twelfth New England Health Institute will meet at the Biltmore Hotel, Providence, R. I., April 21 to 23 under the auspices of the six State Health Departments in New England and their respective health officers. Edward A. McLaughlin, M.D., State Health Officer of Rhode Island, is Executive Chairman.

Among special sessions there will be consideration of cancer, communicable diseases, crippled children, environmental sanitation, health education, industrial hygiene, laboratory, maternal and child health, nutrition, public health nursing, school health, tuberculosis, venereal disease, vital statistics, war preparations, and a meeting of the New England Water Works Association.

NORTHERN CALIFORNIA PUBLIC HEALTH
ASSOCIATION RECOGNIZES CONTRIBU-
TIONS FROM DRS. KELLOGG AND CREEL

THE Northern California Public Health Association held a meeting on March 7 at which time Dr. Richard H. Creel, Medical Director, U. S. Public Health Service, paid a glowing tribute to Dr. W. H. Kellogg who has retired as Director of the State Hygienic Laboratory. It then developed that Dr. Creel was retiring on that very day after 40 years of active service, during much of which he has been a powerful force in public health development in the West. The Northern California Public Health Association then passed the following resolutions:

WHEREAS Dr. Richard H. Creel, Medical Director, U. S. Public Health Service, finishes forty years of active service today and is about to retire from active status; and

WHEREAS more than one-third of these years was spent in valuable service to the Pacific basin and especially to the Pacific Coast; and

WHEREAS his service on this Coast has repeatedly been linked with times of public health crisis with special reference to plague control; and

WHEREAS Dr. Creel has had a long and distinguished service in the field of public health for the Nation as a whole, having joined the U. S. Public Health Service in 1902, in which Service he was advanced through every promotional grade, including Assistant Surgeon General; and

WHEREAS he has been an officer of exemplary and sterling character, prosecuting his duties diligently, unswerving in his determination to uphold the best of public health principles, foregoing the pleasures and rewards of scientific research to devote himself to the application of sound administrative measures; and

WHEREAS in addition to all this, he has been a pillar of strength, a valued colleague, and a courageous leader; now therefore be it

RESOLVED that the Northern California Public Health Association records its appreciation of and high regard for Dr. Creel. We look forward to his continued association with us and his support of progressive public health measures. We wish him the fullest enjoyment of a well-earned measure of leisure and anticipate with pleasure his

continued residence on this Coast and his further participation in our councils.

WHEREAS Wilfred H. Kellogg, Chief of the Division of Laboratories of the California State Department of Public Health, has retired from active work after devoting more than a quarter century of outstanding service to the Department and to the people of the State of California; and

WHEREAS during these years Dr. Kellogg has rendered valuable service in public health administration and in the field of bacteriology and the laboratory sciences as well as being a teacher, counselor, and friend to the public health profession; and

WHEREAS Dr. Kellogg's early recognition of plague and his courageous defense of his findings saved this Coast untold economic and human loss; and

WHEREAS his researches in the laboratory field, especially in diphtheria immunization, have been a great contribution to this State and Nation; and

WHEREAS in particular the State of California is indebted to him for a carefully conceived and well-executed program for certification and high professional standards for laboratory personnel; and

WHEREAS his scientific attitude and knowledge over these many years have exerted a salutary influence on his colleagues, tempering the enthusiasm of the over-zealous, stimulating the imagination of the uninspired and giving renewed determination to the discouraged; now therefore be it

RESOLVED that we record our appreciation of Dr. Kellogg's long continued service, the permanent value of his researches, and his generous support of progressive public health programs. We wish him the fullest measure of satisfaction in his accomplishments and we look forward with pleasure to his continued availability as counselor and friend to his colleagues.

NATIONAL NEGRO HEALTH WEEK

THE 28th anniversary of National Negro Health Week will be held April 5-12. The theme "Opportunities in the National Defense Program for Improvement of Community Health" has been designated the special objective for 1942. Roscoe C. Brown, D.D.S., U. S. Public Health Service, Washington, D. C., is Chairman of the National Negro Health Week Committee.

CITATIONS BY THE AMERICAN SOCIAL HYGIENE ASSOCIATION

THE William Freeman Snow Award for distinguished service to humanity was presented to Frederick Fuller Russell, M.D., Sc.D., Brigadier General, United States Army, at the general session of the 29th Annual Meeting of the American Social Hygiene Association held in Boston, February 3. The presentation was made by Major General Merritte W. Ireland, former Surgeon General, United States Army. General Russell, now Professor Emeritus of the Harvard School of Public Health, and formerly General Director of the International Health Division, Rockefeller Foundation, was instrumental in the first World War in the Army's program for venereal disease control.

The American Social Hygiene Association has conferred honorary life membership on the following leaders in the control of the venereal diseases:

Elizabeth Campbell, M.D.

Bascom Johnson

Joseph Royal Phelps, M.D., Captain U.S.N., Retired

Claude C. Pierce, M.D., Medical Director, U. S. Public Health Service, Retired

John D. Rockefeller, Jr.

Charles S. Stephenson, M.D., Captain, U. S. Navy

HARVARD OFFERS 3 MONTHS' COURSE IN INDUSTRIAL HYGIENE

THE Harvard School of Public Health, Boston, has announced that a course in industrial hygiene open to physicians and engineers will be given from April 27 to August 1. The course will be essentially the same as that given during the past year to three groups of Navy Medical and Engineering officers. The tuition will be \$200. Credit toward a graduate degree in public health or engineering will be given those who successfully complete the work. It is announced that the course will probably be repeated during

the first 3 months of the next academic year, beginning September 21, 1942.

UNIVERSITY OF MISSOURI DEGREES

THE attention of the A.P.H.A. Committee on Professional Education has been called to the fact that the Department of Civil Engineering of the University of Missouri offers graduate courses in sanitary engineering leading to the Master of Science and the Doctor of Philosophy degrees. In the academic year 1940-1941, 10 students were registered for the M.Sc. degree with none for the Ph.D. During this period 7 students received the M.Sc. degree. This information supplements that on degrees and certificates in public health published in the December, 1941, JOURNAL, page 1,306.

DR. FISCHELIS CALLED FOR WAR SERVICE

THE Civilian Supply Division of the War Production Board has asked for the services of Robert P. Fischelis, Phar.D., for part-time service as Chief of the Section of Medical and Health Supplies of the Civilian Supply Division of the War Production Board. Dr. Fischelis has been Secretary and Chief Chemist of the New Jersey Board of Pharmacy and is a member of the New Jersey State Board of Health. He will organize a staff of specialists and consultants in the field of hospital, medical, and drug supplies at the Washington Office of the War Production Board.

PERSONALS

Central States

GEORGE W. BASSOW, M.D., of Steubenville, Ohio, has resigned as Health Commissioner of Jefferson County, to return to private practice in Massachusetts.

JOSEPH L. BRYAN, M.D.,† of Xenia, Ill.,

† Member A.P.H.A.

of the Flora office, will take over the work in Hamilton and White Counties, included in this district.

FORDER F. DEMUTH, M.D., of Hicksville, Ohio, has been reappointed Health Commissioner of Defiance County, succeeding HENRY C. LINDERSMITH, M.D., of Sherwood, resigned.

WILLIAM H. DRISSEN, M.D., of Port Washington, Wis., has been reappointed Health Officer of Ozaukee County.

HAROLD J. GORDON, M.D., for a number of years in charge of the venereal disease program of the Akron Health Department, has been appointed Venereal Disease Control Officer of the Ohio State Department of Health.

BEATRICE A. T. HAGEN, M.D., of Zanesville, Ohio, who has been Health Commissioner of Muskingum County for 12 years, has been reappointed for a one year term. She is also Secretary of the Muskingum County Academy of Medicine.

HAROLD J. HALLECK, M.D., of Winamac, Ind., was recently appointed Health Commissioner for Pulaski County for a term of 4 years.

ROY W. HARRELL, M.D.,† of Carbondale, Ill., will take over the work in Williamson, Saline, Gallatin, and Franklin Counties.

CHESTER S. HEIMLICH, M.D., of Attica, Ohio, has resigned as Health Officer of Seneca County to devote his full time to private practice.

EDWARD D. HUDSON, M.D., has been appointed Health Officer of Lake Geneva, Wis., to succeed LAWRENCE H. DONATH, M.D., who resigned to transfer his medical practice to Milwaukee.

ALEXANDER S. MACK, M.D., of Oak Harbor, Ohio, has been reappointed Health Commissioner of Ottawa County.

CLIFFORD H. MAYFIELD, M.D.,† of Reynolds, Ind., has been reappointed

Health Officer of White County for a 4 year term, beginning January 1.

RANSLEY J. MILLER, M.D., of Topeka, Kans., has been appointed Acting Secretary of the Topeka Board of Health, to succeed Dr. CHARLES B. STEPHENS, who resigned.

KENNETH F. PREFONTAINE, M.D., of Slinger, Wis., has been appointed Health Officer for the Village of Slinger; he occupies the same position for the village of Polk.

BENJAMIN L. SARGENT, M.D., has been appointed Health Officer of Park Ridge, Ill., to succeed the late Dr. IRVIN J. PASCOE.

FRANK TERNOCKY, JR., M.D., of Bloomville, Ohio, has been elected Health Commissioner of Seneca County.

HOMER S. WEST, M.D., Clairsville, Ohio, has been appointed Health Commissioner of Belmont County, filling the vacancy that occurred when Dr. WILLIAM B. BAILEY, now of Morgantown, W. Va., resigned.

ROBERT G. WHITE, M.D.,* becomes Director of the Division of Preventable Diseases of the North Dakota State Department of Health. At present Dr. White is District Health Officer of the District Health Office in Valley City, N. D.

Eastern States

LEONA BAUMGARTNER, M.D., PH.D.,* has been appointed as Director of the Bureau of Child Hygiene of the Department of Health, New York, N. Y. Dr. Baumgartner, who has been Acting Director of the Bureau since January 1, 1941, was first in the civil service examination recently held for this position.

HUGH H. DARBY, M.D., Columbia University, New York, scientist and author of many authoritative works, has joined the staff of the Borden Vitamin

* Fellow A.P.H.A.

† Member A.P.H.A.

Company, for research and development in the production and application of vitamins and hormones.

WILLIAM B. FULTON, M.D., M.P.H.,* Senior Surgeon in the U. S. Public Health Service Reserve and a former director of the Bureau of Industrial Hygiene of the Pennsylvania Department of Health, was recently announced as Chief of the Health Division in the Bureau of Mines, Department of the Interior.

FRED LAURENCE MOORE, M.D., M.P.H., has been appointed Director of the Division of Health Studies of the Commonwealth Fund, New York, N. Y., succeeding the late Watson Frank Walker, Dr.P.H.. Dr. Moore received his medical degree at Dalhousie in 1924. For some years he was health officer of Sullivan County, Tenn., and is a graduate of Johns Hopkins School of Hygiene and Public Health with an M.P.H. in 1934. Since 1939 he has been Associate Professor and Professor in the Department of Preventive Medicine, at Long Island College of Medicine, Brooklyn, N. Y.

DR. WILLARD C. RAPPLEYE, Commissioner of Hospitals of the City of New York since October 1, 1940, has given up his city post to return to his duties as Dean of the College of Physicians and Surgeons of Columbia University, New York. Dr. Rappleye took the post in 1940 on a temporary basis.

PROFESSOR G. M. RIDENOUR † has been appointed Associate Resident Lecturer on Public Health Engineering at the School of Public Health, University of Michigan, Ann Arbor. Professor Ridenour was formerly Associate Professor of Sanitary Engineering at Pennsylvania State College.

MILTON ROSE, M.D., DR.P.H.,† has

been appointed Medical Director of the Pacific Coast Area of the American Red Cross, with headquarters in San Francisco, Calif., as announced by Chairman **NORMAN H. DAVIS** of the American Red Cross in Washington. Dr. Rose, who is a graduate in medicine and public health from Yale, was Assistant Professor of Physiology at the University of California and Assistant Director of the School of Public Health at the same institution. He has most recently been Professor of Public Health at the University of Pennsylvania, in Philadelphia.

HERMAN G. WEISKOTTEN, M.D.,* Dean of the Syracuse University College of Medicine, Syracuse, N. Y., has been appointed Secretary of the Council on Medical Education and Hospitals of the American Medical Association, Chicago, to succeed the late **WILLIAM DICK CUTTER, M.D.** Dr. Weiskotten, who was Commissioner of Health of the city of Syracuse 1926-1928 and who has been Professor of Preventive Medicine at Syracuse University, is a member of the New York State Public Health Council, a member of the Executive Committee of the State Committee on Tuberculosis and Public Health of New York, and a Fellow of the American Public Health Association. He recently collaborated with the late Dr. Cutter in a personal inspection and survey of medical colleges in the United States and Canada.

Southern States

AARON WILSON BROWN, M.D., of Richmond, Va., recently resigned as full-time Venereal Disease Control Officer of Richmond, to locate in Pocahontas. He was the first to hold this position. **ANDREW B. COLLEY, M.D.,†** of Dixon, Ky., has succeeded **GEORGE B. DAVIS, M.D.,** as Health Officer in Grayson County. Dr. Coley will divide his time between Grayson and Hart Counties, with headquarters in Leitch-

* Fellow A.P.H.A.

† Member A.P.H.A.

field, and Dr. Davis will move to Connecticut, it is reported.

LELAND H. DAME, M.D.,† has resigned his position as Director of the Highlands-Glades County Health Department, and has accepted appointment as Director of the Seminole County Health Department, with headquarters at Sanford, Fla.

LORENCE W. FELLER, M.D., of Fredericksburg, Tex., has been named Health Officer of Gillespie County, to succeed the late JOSEPH E. PEDEN, of Fredericksburg.

JOHN D. FOUTS, M.D., of London, Ky., Health Officer of Laurel County, has been appointed Director of Venereal Disease Control for the city of Louisville.

EDWARD S. GRADY, M.D., of Winston-Salem, N. C., has been placed in charge of the health unit in Johnston County, succeeding WILL H. LASITER, JR., M.D., of Smithfield, resigned. Dr. Grady has been Assistant Health Officer of the unit covering Forsyth, Stokes, Yadkin, and Davie Counties.

LOYD M. GRAVES, M.D.,* Memphis, Tenn., has been named Director of the Memphis and Shelby County Health Departments, recently consolidated.

RUTH E. GROUT, PH.D.,* Senior Supervisor of Health Education, Department of Health and Safety, Tennessee Valley Authority, Chattanooga, has been appointed Assistant Professor in Preventive Medicine and Public Health at the University of Minnesota, as announced by GAYLORD W. ANDERSON, M.D., Professor and Head of the Department of Preventive Medicine and Public Health, Minneapolis. Miss Grout will begin her work with the University of Minnesota with the fall term.

JOHN H. MUSSER, M.D., Professor of Medicine, Tulane University of Louisiana School of Medicine, New Orleans, La., has resigned as President of the State Board of Health, effective February 1.

LOWELL J. REED, PH.D.,* Professor of Biostatistics and Dean at the Johns Hopkins School of Hygiene and Public Health, Baltimore, Md., has been appointed Chairman of a National Commission on Vital Records established at the request of the Association of State Health Executives and the American Association of Registration Executives under the Health and Medical Committee of the Office of Defense, Health and Welfare Services.

SEBORN C. RICHARDSON, M.D., of Bryan, Tex., has been named Health Officer of Bryan.

EDWIN BRUCE UNDERWOOD, M.D., has been placed in charge of the Webster County Health Department, Dixon, Ky., to succeed ANDREW B. COLLEY, M.D.

LUTHER P. WALTER, M.D., formerly of El Paso, Tex., is now Director of Jefferson County Health Unit, Port Neches, Tex.

THOMAS WILSON, M.D., of Wynne, Ark., has been elected President of the Arkansas State Board of Health.

C. L. MENGIS, M.D., has been appointed, effective February 1, Director of the Louisiana State Board of Health, succeeding JOHN H. MUSSER, M.D., who has served in this position since September, 1940. Dr. Musser resigned in order to give full time to his work as Professor of Medicine at Tulane University. Dr. Mengis, formerly Head of the Bureau of Crippled Children in the Louisiana State Department of Health and recently Director of Iberia Parish Health Unit, will be assisted by DR. ROBERT H. ONSTOTT, Executive Officer, staff member of the U. S. Public Health Service, and DR. FORD S. WILLIAMS,

* Fellow A.P.H.A.

† Member A.P.H.A.

Assistant State Health Officer. Dr. Mengis is a graduate of Tulane University and was trained in public health at Vanderbilt. For 5 years he was associated with the U. S. Public Health Service, following which, according to the press, he was in private practice for 24 years.

Western States

DR. I. O. CHURCH,* for some years County Health Officer with the Alameda County Department of Health, San Leandro, Calif., has resigned to accept a position as Director of the Branch County Health Department, Coldwater, Mich., under the auspices of the W. K. Kellogg Foundation, effective February 1.

FRANK J. CRANDALL, JR., M.D.,* formerly Epidemiologist for the Los Angeles City Health Department, is now Lieutenant-Colonel in the Medical Corps of the U. S. Army, serving as Medical Inspector for Camp San Luis Obispo, Calif.

AGNES M. ENGLISH, M.P.H.,† Health Education Consultant with the Wyoming State Department of Public Health, Cheyenne, has resigned to accept an appointment as regional nutrition representative of the Office for Emergency Management. After a training period in Washington Miss English will be assigned to the XII Social Security Region, which includes Arizona, Colorado, Idaho, Utah, and Wyoming, with headquarters in Denver.

ROBERT M. MATTS, M.D.,† of Yuma, Ariz., Director of the Yuma County Health Service, has been called into active service.

ABE L. SCHEFF, M.D., formerly of Rosedale, Miss., Passed Assistant Surgeon, U. S. Public Health Service, Reserve, has been appointed Director

of the Santa Cruz Health Service, which on January 1 ceased to be a part of Health District Number 1.

Foreign

DOMINGO RAMOS, M.D.,* Havana, Cuba, was appointed Minister of Health and Welfare of Cuba by President Fulgencio Batista on February 2. Dr. Ramos has for some years been serving as Minister of War.

Death

WALTER S. FRISBIE,* Chief of the Division of State Coöperation, Food and Drug Administration, Federal Security Agency, Washington, D. C., died suddenly on February 19 after a heart attack while at work. Entering the federal service in 1921 as Chemist in charge of the Office of State Coöperation, he advanced to the position which he held at the time of his death, in which he was widely known among officials engaged in food and drug control work. A graduate in 1901 from Yale, he had pursued graduate studies in chemistry at Yale, Cornell, and Johns Hopkins. He had previously served in Iowa and Nebraska. He became a member of the Association in 1925 and a Fellow in 1930 and was identified with the Food and Nutrition Section. He was Vice-Chairman of the Food and Nutrition Section in 1936, Chairman in 1937, and for a number of years a member of the Committee on Research and Standards.

A Mock Epidemic of Typhoid Fever Used in Public Health Training*

GEORGE B. DARLING, DR.P.H., F.A.P.H.A., AND
LIEUTENANT COLONEL LEON A. FOX, M.C., F.A.P.H.A.

*W. K. Kellogg Foundation, Battle Creek, Mich.; and U. S. Army,
Division of Engineering, Eastern Division 2, Washington, D. C.*

THE W. K. Kellogg Foundation has been coöperating for a number of years with the citizens of seven counties in southwestern Michigan—Allegan, Barry, Branch, Calhoun, Eaton, Hillsdale, and Van Buren—in a joint effort to improve the health, happiness, and well-being of children. This program is called the Michigan Community Health Project. It is built around the seven county health departments.

Few health officers have any actual experience with epidemics. No way exists to test plans, or technics, or to gain experience in the proper use of the necessarily extraordinary powers invoked at such times. In a real epidemic mistakes are costly, often tragic, and decisions have to be made under tremendous pressure. This is also true of war, and yet military forces are trained in actual maneuvers in war games. Could similar technics be developed to make mock epidemics useful in staff training?

The seven county directors agreed that an experiment should be tried. A Foundation executive was asked to arrange the problem, all details of which were to be secret except the date of onset. An army medical officer was invited to help prepare and direct the problem to provide both a broad experience in epidemiology and laboratory methods and a knowledge of war game technics.

OBJECTIVES

General objectives were discussed. Could a mock epidemic—

1. Train public health personnel for their respective rôles in epidemics?
2. Point out potential local channels through which epidemics could spread?
3. Test the adequacy and quality of facilities including laboratories?
4. Educate community groups to their public health responsibilities?

Typhoid fever was chosen for the first experiment. This decision was carefully guarded. Secrecy was necessary if the difficulties that exist in epidemiological investigation were to be reproduced even in part.

* Read before the Epidemiology Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

munities for potential danger spots. Many possible channels of infection known to the problem directors were eliminated by the health departments during this period.

The problem directors gave their preparations a final check in August. Necessary supplies were obtained. Arrangements were completed for a laboratory for the preparation of specimens. Guest books were left at roadside stands and resorts to be signed by all patrons during the period of theoretical exposure. Cases to be released were spotted on maps. A master chart was prepared for the problem directors which gave the exact times and methods to be used in releasing the cases and special instructions applying to the general situation. The case histories were keyed to this chart with a code number and filed in envelopes to be given the control agents of the appropriate counties on the dates specified. Procedures were outlined and instruction sheets made ready. New stories were prepared so that the public could cooperate on an intelligent basis and not misunderstand the project.

The preparations were complete.

THE SPARK

About the middle of August, a dinner meeting was held for food handlers from all seven counties. The program included a discussion of milk production and the importance of the food handler in the control of communicable disease. Later, members of the health department staffs were excused from the meeting, and after the food handlers were pledged to secrecy, the proposed mock epidemic was described and its purpose explained. All those present agreed enthusiastically to cooperate with the problem directors and to furnish health department investigators with complete information regarding their activities if called upon.

The menu included a number of

old epidemiological favorites—cottage cheese, roast turkey with oyster dressing, whipped potatoes in cream, mashed squash, tossed salad, a chocolate éclair, and milk. Each person at the dinner signed his printed menu, scratched out any items he had not eaten, and turned it in. This record of food actually eaten by guests was made to establish definitely exposure to the theoretically infected food and to serve as a control over later epidemiological investigations.

On August 31, Colonel Fox arrived. A meeting was held with the fellows in public health engineering who were to serve as control agents and laboratory agents. Supplies were distributed and these men took their posts in the counties. The problem had begun.

THE EXPLOSION

From September 1 through 4, several cases of diphtheria, chicken pox, and other communicable diseases were reported to each county health department. These reports had no connection with the real problem. They prevented immediate identification of the nature of the epidemic, and served as a check on the efficiency of the control and reporting system. During this same period 10 cases of typhoid fever were also reported. These 10 cases were scattered through the counties and had one factor in common—they had all attended the special food handlers' dinner in August. Of some 323 guests invited to attend from the seven counties, approximately 40 theoretical cases of typhoid fever eventually developed.

Sporadic cases occurred in all counties. Some of these cases were in health department personnel, requiring transfers of responsibilities. Some caused alarm and apprehension concerning the possible development of secondary outbreaks which failed to appear.

Four secondary outbreaks became manifest due to ambulant or walking typhoids who contracted infection at

the dinner but remained on duty in dairies and food establishments. Outbreaks occurred in two raw milk dairies. A food handling outbreak resulted from a service club dinner, and a massive infection in a large children's home produced secondary cases in spite of previous immunization. One roadside restaurant spread the infection to distant points through tourists and bus travellers. The guest book showed that individuals from 32 states and Canada and points as far away as Shanghai, Rio de Janeiro, and the Canal Zone were exposed during the few days involved.

The mock epidemic was getting nicely started when the field exercise was terminated at 6:00 P.M. on September 10.

THE MACHINERY BEGINS TO WORK

Coöperative individuals who had attended the August dinner reported themselves ill to the health department or were reported by IMPersonated physicians. Field investigations were made exactly as though the persons were really sick. Epidemiological reports cleared through the control agents. Supplementary case histories were delivered. Empty, properly labelled containers were turned in, giving notice of intention to take laboratory specimens. After due lapse of time the laboratory agents returned these containers to the health departments with specimens appropriate for the predetermined theoretical case histories. Laboratories ran the specimens in the usual way. The health directors wrote out specific orders for control measures and filed them with the control agents, who brought them in to the judges in the evening.

The essential facts about the reported cases were quickly pooled by the seven county health officers, and the connection with the food handlers' dinner in August was shortly established.

STUDENT TRAINING

A fellow in public health administration was asked by the county directors to investigate the food handlers and the food served at that dinner. He made a complete investigation of the hotel, pastry shops, and other places involved, including the ice plant. He uncovered cross-connections, incomplete pasteurization of the milk products, and other interesting potential hazards. Each item of the food was traced, and occasionally conditions were experimentally reproduced. For example, another turkey was prepared in the same kitchen. Temperatures were taken of the oyster dressing both during the preliminary cooking and while the turkey was being roasted. Results showed that the processes used would not kill any pathogenic bacteria present. Theoretical specimens were taken of all food handlers who had helped prepare the dinner. The infection was finally traced to a man who prepared the filler for the chocolate eclairs.

LABORATORIES

The problem tested the regular county laboratory facilities as well as the health department's knowledge of how to use them. One laboratory was swamped with routine analyses, and confirmation tests were difficult to obtain when they were most needed. Laboratory technics were brought up to date. New media for making shorter differential diagnoses were tried out.

After enough samples had been run through the county laboratories to serve the purpose, the IMP state laboratory undertook to do all the laboratory work on paper without actual samples, but with proper time allowance. One of the problem directors took the place of the laboratory director and reported the scientific results directly to the county directors. This made it possible to evaluate the health director's interpretation and use of such data.

The exercise demonstrated the need for additional laboratory services in the area in time of epidemics.

THE PRESS

To test the ingenuity of the county directors in dealing with a hostile press, scare stories were released in extras, sample copies of which were actually run by cooperating newspapers and placed on the desk of the director without warning. The staffs then had to deal with a theoretically excited public and antagonistic press.

RECORDS

During the last two days of the problem, the health departments were required to work only from their own office records so that the value and completeness of these records could be tested. During this stage raw milk routes became involved. The elimination of field visits kept the customers from being unduly alarmed as a result of the health department's activities.

EDUCATION OF MILK DEALERS

Visits were made, however, to the milk plants involved, and the conditions that had theoretically developed were explained when the histories were taken.

One dairy found to its chagrin that its recording thermometer had broken down and there were no records to prove that pasteurization had occurred during the days when the milk might have carried the disease to their customers. For the first time the manager understood how this device protected him as well as the public.

Many food handlers who were quite conscientious about not working when they were sick had not recognized the danger of passing on an infection during the incubation or pre-symptom stage or the potential danger of a healthy carrier.

Under the emphasis and enthusiasm

of the game in which they took part, the lay people understood the need for the health department regulations as they never had before.

LAWS OF CHANCE

The use of real people proved of inestimable value in producing unpredictable situations. For example, one secondary outbreak was caused by the fact that no control measures were taken at a resort since the cook who had attended the August dinner had resigned and had been replaced by another person. The hurried investigation made by the health department failed to disclose that the cook had stayed long enough to expose a large number of people at a 3 day meeting, and a second outbreak occurred. Events of this type gave the problem a realism that could be achieved in no other way.

JUDGES EVALUATE METHODS

The judges reviewed the action taken by the invading organisms and the health department staffs each day. They traced the epidemic on their own charts and prepared statements on the relative effectiveness of procedures chosen by health departments for control. These comments formed the basis of the discussion at the staff critique on the day following the conclusion of the problem.

CRITIQUE

This critique was attended by the judges, the problem directors, county health directors, the Foundation consultants, the Michigan State Health Commissioner, and representatives of the U. S. Public Health Service. A history of the outbreak as it would have been officially recorded was presented by the problem directors, illustrated with complete charts and tables. The judges led the discussion of the relative effectiveness of the various

suitied to serve as indices of sanitary quality for Connecticut market cream.

During that part of the study previously reported, the samples (approximately 75 per cent of the final total) were plated in triplicate, using "Standard Methods" glucose tryptone skim milk agar. One set of plates was incubated at 37° C. for 48 hours; another set, at 55° C. for 48 hours; a third set, at 8° C. for 4 days. Charts of recording thermometers indicate that the 37° C. incubation was actually conducted within the range 35°–37° C., with the upper limit a maximum reading never recorded during more than a small fraction of the incubation period. The remaining cream samples (25 per cent) received this same treatment, supplemented by a fourth set of plates incubated at 20° C. for 48 hours. Direct microscopic clump counts were made on all samples. All the samples of pasteurized cream were inoculated into brilliant green lactose bile (2 per cent) for the determination of coliform organisms and were tested for phosphatase.

The cream samples were of three types:

1. Raw retail cream samples. These had received no heat treatment.

2. "Import" cream samples (many pasteurized or heat-treated at the source). It is required by law that these be pasteurized within Connecticut before being offered for sale on the retail market, whether or not they have been pasteurized elsewhere.

3. Retail pasteurized cream samples. These include both cream produced locally and im-

ported cream after pasteurization in Connecticut. A considerable proportion of the latter group may have been repasteurized.

Table 1 shows the percentage of samples which failed to meet the standards (exceeded a limiting value of 500,000 per ml.). The legal plate count standard at 37° C. for 48 hours in Connecticut is 500,000 colonies per ml. and in this study we have accepted that figure as the limiting value for plate counts made at the other temperatures, and for microscopic clump counts.

The direct clump count failed many more samples than did plate counts at any temperature except in the case of the small number (40) of raw retail cream samples for which a 20° C. plate count gave results comparable to the clump count. The percentage of failures by the clump count was relatively uniform for all three types of samples.

A few samples of frozen cream, some 2 or 3 months old and one 53 weeks old, were included among the samples tested. None of these gave a high count by any method.

The results obtained by the standard plate count at 37° C. would, by themselves, give the impression that good cream was being imported but that raw and pasteurized retail cream was of only fair quality. Judged by this standard, all three types of cream were of much better quality than was indicated by the direct clump counts.

TABLE 1

Results of Tests on 730 Samples of Raw, Import and Retail Pasteurized Cream

Test	Raw		Import		Retail Pasteurized	
	Total	% Failing *	Total	% Failing *	Total	% Failing *
37° C.—48 hours plate count	149	30.8	336	12.5	245	24.4
55° C.—48 hours plate count	149	0	336	6.5	245	4.8
20° C.—48 hours plate count	40	47.5	138	28.2	84	29.7
8° C.—4 days plate count	149	29.5	336	19.0	245	30.2
Direct microscopic clump count	149	45.6	336	44.6	245	53.8
Tests for coliform organisms	302	59.2	217	72.3
Phosphatase test	310	4.1	234	12.3

* Having counts over 500,000 per ml.; showing coliforms present in 1 ml. or less; or having phosphatase values greater than 0.05 mg. phenol by the Gilcreas-Davis modification of the Kay-Graham test.

Results of 55° C. plate counts showed the thermophilic group of organisms to be of minor importance, although a slight tendency toward an increased incidence of these forms was observed in the retail pasteurized group. Recalling that much of the cream in this group had been twice subjected to pasteurization, the observed increase was less than had been anticipated.

Results of counts at incubation temperatures of 8° C. and 20° C., contrasted with the findings by 37° C. incubation, indicated the presence in the samples of appreciable numbers of organisms capable of growing at refrigerator temperature but probably having optimal growth temperatures confined to the lower portion of the range ordinarily assigned to the mesophilic bacteria (in the neighborhood of 20° C.). This is particularly true of samples giving high counts. Limitations of time and facilities made it impossible to make plate counts at 32° C. but it is improbable that this variation from the 35°–37° C. range would have effected any change in these conclusions.

The results of the tests for coliform organisms seem to indicate that an undesirable situation must have prevailed generally in the handling of market cream after pasteurization, since the phosphatase tests did not show a surprisingly high percentage of under-processed cream. It is very significant that the results of the direct counts reflected this situation to a much greater degree than did plate counts at any temperature.

The type of flora found in the high count cream samples deserves special notice. Samples with high direct counts but low plate counts showed a mixed flora on direct examination, but the majority were observed to contain forms simulating the vegetative cells of spore-forming rods, often in large numbers. The same morphological type of organism was frequently observed also in

samples giving both high clump and high plate counts. Organisms isolated from plates incubated at 8° C., 20° C., and 37° C. were not, however, of this type but were usually of three groups: lactic types, coliforms, and pseudomonads. This last group was isolated frequently from the 20° C. plates but very seldom in large numbers from any one sample.

In the case of pasteurized samples, these observations could be explained in one of the two following ways: (1) The rods observed in direct smears were organisms which had been killed by pasteurization but had retained affinity for methylene blue; or (2) these were live forms, incapable of growth under incubation conditions to which they were subjected. It is pertinent that like forms with similar behavior were found in raw cream, although in fewer numbers. If these were viable forms of sporogenic bacilli, as their morphology suggested, the failure to initiate growth on "Standard Methods" agar is not surprising, since the reaction of spore-formers to a changed environment is little understood and entirely unpredictable unless confined to a narrow range of experimental conditions.

• SPORE FORMERS IN MARKET CREAM

It was decided to test certain of the factors influencing the development of spore-forming rods occurring under market conditions in cream. The inoculation of pure cultures into sterile cream was not considered of as much value as a study of behavior of sporogenic types comprised in the "natural" inoculum. Therefore, a series of cream samples was heated to 80° C., held there for 30 minutes, and then cooled immediately. A microscopic clump count was made on each sample, which then was divided aseptically into two portions. One portion was placed in the icebox (6–8° C.); the other was incubated at room temperature. The portions of cream held

in the icebox were examined by direct count at the end of 24, 48, and 72 hours, and at the end of the 6th and 7th day. Microscopic clump counts on the portions held at room temperature were made at hourly intervals during the first 11 hours and also after overnight incubation (about 21 hours). The results of this experiment are summarized in Table 2.

observed was the same as that found after storage at room temperature. Certain samples (979, 980, 981, 984), however, showed no increase in count when held for a full week in the refrigerator, but in every case these were samples containing relatively few resistant forms originally as shown by low counts made immediately after heat treatment. A further observation may be made

TABLE 2
Effect on the Direct Microscopic Clump Count of Heating Cream at 80° C. for 30 Minutes and of Subsequent Incubation at Room Temperature and at 8° C.

Sample Number	Before Heating	After Heating	Direct Microscopic Clump Count per ml.							
			Incubation at Room Temperature for					Incubation at 8° C. for		
			3 hr.	6 hr.	9 hr.	11 hr.	21 hr.	48 hr.	6 da.	7 da.

The microscopic picture presented by the heated cream when held at room temperature was that of spore-forming bacteria undergoing rapid vegetative development. The first sharp rise in numbers occurred sometimes as early as the 6th hour, sometimes at the end of 8, 9, or 10 hours. As the count increased, the number of organisms per clump also increased. The similarity of the organisms to those previously described as present in market cream was striking. The morphological types of bacilli which developed during room temperature incubation of these heated samples grew well on plates incubated at 20° C. The ability of certain of these spore-forming organisms to grow in cream at low temperature (6–8° C.) is shown beyond question of doubt by samples 982 and 985. The type of organism

from Table 2, with regard to the staining behavior of organisms after being subjected to killing temperatures, by comparing direct counts made before heating the cream with counts made afterward. With the exception of sample 979, which had a low count in the beginning, all samples showed a reduction in the number of clumps of bacteria capable of taking the stain. The reductions ranged from 39 to 95 per cent depending, apparently, upon the number of organisms in a heat-resistant stage at the time of heating. Similar reductions in direct counts have been noted in our laboratories in milk samples subjected to laboratory pasteurization.

DISCUSSION

Determination of the sanitary quality of cream can conceivably be made by

using one or more of three general procedures: (1) Enumeration of the total bacterial population, (2) enumeration of special types of bacteria, or (3) determination of the degree to which bacterial growth has affected the product. This study is concerned primarily with the first procedure, since the others, although valuable, are but supplementary to it.

So long as the method chosen for enumeration of total bacterial population is rigidly standardized, precise enumeration need not be the ultimate goal. On the other hand, it is essential to have reasonably accurate knowledge of the extent to which results of a laboratory test must be qualified. It is our contention that the direct microscopic count offers the most logical and most fundamental approach to the problem and that its use will result in better control of the product under test by furnishing knowledge of the types of organisms responsible for an unsatisfactory product.

All plate counts, whether made under conditions specified in "Standard Methods" or under modified conditions, have limitations which can exercise an effect over a range too broad and unpredictable to permit a sufficiently exact interpretation of results. Our results indicate that selection of lower temperatures for incubation of plates made from cream samples results in counts more nearly in agreement with the direct microscopic clump count.

Objection may be raised concerning the validity of a direct count on a sample which has been subjected to pasteurization. The single strong objection to this method is the possibility that killed bacteria may be counted. While this objection cannot be discounted entirely in the absence of experimental evidence to the contrary control officials regard it too seriously since the aim of control is as much to subject a good product to pasteuriza-

tion as to insure a satisfactory and safe final product.

In answer to this objection, our results suggest that the average period of cold storage of samples prior to examination in a public health laboratory establishes conditions under which only a minimum number of bacteria of questionable viability will stain. In our experience, borderline microscopic counts are rarities if a standard of 500,000 clumps per ml. is used. Counts are either well below or far above that figure. This is significant when we consider the experimental work on milk of Hastings and Dayenport⁴ who demonstrated that a decrease in microscopic count occurs after pasteurization, that the decrease in many cases is a large one and that further decrease may occur during storage at low temperatures.

Even when the phosphatase test proves pasteurization to have been performed effectively, a high direct count on a cream sample justifies one of the following conclusions: (1) The product was of poor bacteriological quality when sampled, as a result of improper handling, or (2) it was an inferior product before pasteurization. Either of these conclusions provides adequate reason for control officials to require corrective action. The results of tests for coliform organisms on the series of samples included in this study lead us to believe that the former conclusion will, in general, prove to be more probable. In our study, coliform organisms were present in market cream to an extent which cast serious doubt upon the efficiency of methods of handling and storing following pasteurization. This is not surprising, since no regulations are in effect in Connecticut to require refrigeration of cream at all times between pasteurization and sale or to limit the age of cream which may be offered for sale. Consequently, chances of bacterial multiplication are often as great in pasteurized cream as in raw cream particularly

if thermoduric mesophiles are present.

The demonstration in direct counts on cream of organisms morphologically similar to the sporogenic bacilli is strikingly similar to observations made on milk by Robertson, Yale, and Breed.⁵ Those authors were unable to grow these organisms from pasteurized milk by ordinary plating methods, although their presence was noted in direct smears.

We have shown that market cream may contain considerable numbers of spore-forming organisms in a heat-resistant stage, but in no case were we able to isolate by plating methods more than an occasional spore-former, even though large numbers of colonies were fished and examined. Therefore, we believe the direct microscopic count is the best method for detecting these bacilli, which we have shown capable of producing in cream enormous numbers of progeny, in the absence of or even in the face of storage at refrigerator temperatures.

SUMMARY AND CONCLUSION

Results of a comparative study of methods for the enumeration of bacteria in raw and pasteurized cream offered for retail sale indicate that the direct microscopic clump is the most satisfactory and practical method for this purpose, especially if the sample, when pasteurized, is supplemented by a coliform determination and a phosphatase test. The standard plate count (35°–37° C. incubation) is less satisfactory than plate counts made at incubation temperatures of 8° C. and 20° C. Plate counts at 55° C. for thermophilic organisms were of significance for certain samples but had little value for routine testing.

Experimental evidence is cited to show that market cream may contain appreciable numbers of sporogenic bacilli able to survive for 30 minutes temperatures considerably higher than that of pasteurization. These organisms are capa-

ble of rapid development in cream at room temperature (20° C.) and in many cases, of multiplication at a somewhat slower rate at refrigerator temperature (8° C.). These organisms are detected by a direct microscopic count, but do not ordinarily produce colonies on plates of "Standard Methods" agar incubated at 8° C., 20° C., or 37° C., and only rarely develop at 55° C. Consideration of the manner of distribution of cream on the retail market in Connecticut shows these observations to be of great importance.

The contention that bacteria killed by pasteurization may be counted by the direct method is of little practical significance when consideration is given to the fact that direct clump counts are almost invariably either well below or far above fair limiting values for judging sanitary quality. A direct count in millions per ml. indicates that a cream either contains an extremely large number of viable bacteria or was an inferior and unsanitary product before pasteurization. Furthermore, when large numbers of sporogenic rods are present, it is probable that the bacteria observed are viable, since pasteurized cream is very frequently distributed under conditions which are favorable to the growth of these thermoduric bacteria.

The main advantage of the direct count over the standard plate count, besides ease of manipulation, is the procurement of data on types of organisms present, giving directional guidance to corrective control measures. Furthermore, in a large number of cases, the results of the direct count agree with results of coliform tests that indicate improper handling after pasteurization when plate counts seemingly indicate cream of good quality.

Considering the advantages and the limitations of the direct microscopic clump count as contrasted with those of a standard or a modified plate count, the direct count is superior as an index

of the sanitary quality of market cream, whether raw or pasteurized.

San Francisco's Pasteurization Ordinance Finally Upheld

IT has been reported by J. C. Geiger, M.D., Director of Public Health in the City and County of San Francisco, that an ordinance banning the sale of milk in San Francisco, except certified, unless it was pasteurized, which was passed in 1933 by the Board of Supervisors, was finally upheld as a proper exercise of the police power by a decision of the Supreme Court of California rendered April 2, 1942.

Outlining the development of this legislation, Dr. Geiger stated that the request for the pasteurization of all milk supplies, except certified, was brought to a focus by the situation existing in San Francisco in 1932, at which time approximately 2 to 3 per cent of the fluid milk supply was of a raw grade designated as guaranteed, and that tuberculin testing of animals was not universal or complete.

The Director of Public Health barred the distribution of guaranteed raw milk because of the fact that the inspection given by the Department of Public Health to dairy farms producing this type of raw milk was inadequate and, therefore, the production, handling, and distribution of guaranteed raw milk created a potential danger to the public health. Under the then existing condi-

tions, sufficient personnel to cover the duties imposed on inspection services necessary to safeguard the production, handling, and distribution of raw milk was not available. In the case of the production, handling, and distribution of certified milk, the inspection service provided by the Milk Commission of the San Francisco County Medical Society was entirely adequate, and the inspection service was frequent and performed by dairy veterinarians and physicians. This type of milk was later pasteurized and finally voluntarily eliminated.

The Natural Milk Producers Association, an organization composed of grade A raw and guaranteed raw milk producers, contested the ordinance of 1933 banning the sale of raw milk, except pasteurized, by applying to the Superior Court for a permanent injunction. This was denied in 1933. In 1938 the Superior Court upheld the ordinance and in 1941 the District Court of Appeals unanimously affirmed this decision. In upholding the provisions of the ordinance the Supreme Court in its 1942 decision stated: "It cannot be doubted . . . that the requirement that all milk for human consumption be pasteurized is a proper police regulation."

The Nasopharyngeal Swab in the Diagnosis of Pertussis*

T. M. SAITO, JOHN J. MILLER, JR., M.D., AND
CHARLES W. LEACH, M.D.

*Department of Pediatrics, Stanford University School of Medicine,
San Francisco, Calif.*

BRADFORD, Slavin, and Brooks^{1, 2} have adapted the nasopharyngeal swab, which has been routinely used in the diagnosis of pneumonia, to the diagnosis of pertussis. The purpose of this communication is to compare the results obtained by this new method with that of the cough plate originally described by Chievitz and Meyer³ in 1916. There have been numerous reports on the latter method.⁴⁻¹⁷ It has been found highly satisfactory in the hands of the experienced but has not come into general use. Difficulties have been (1) inducing a cough at the time one has the plates (particularly difficult in infants), (2) transporting the plates, and (3) identifying *Hemophilus pertussis* on a plate crowded with colonies of other microorganisms. Another common problem is that of having sufficient sheep or horse blood available to make the media.

The nasopharyngeal applicator advised by Bradford and Slavin and used by the writers is "a small bit of cotton tightly wrapped about the end of a thin, flexible copper wire." It is passed through a nostril into the nasopharynx. Therefore, it must be much smaller than the usual swab used for taking nose and throat cultures for diphtheria. Great gentleness is required. The child's head

must be immobilized. If resistance (a large turbinate, deviated septum or adenoids) is encountered, the applicator should be withdrawn and inserted in the other nostril. It is, of course, sometimes quite impossible to pass even the smallest applicator.

The insertion of the applicator into the nasopharynx very often induces coughing. The applicator should be left there for two or three of the coughs. Incidentally this procedure is a very effective one for obtaining well exposed cough plates. We have usually exposed them at this time. The applicator is then withdrawn and placed in a sterile test tube.

Petri dishes of Bordet-Gengou medium (the same as used for cough plates) are then inoculated lightly by touching the medium three times with the applicator. A sterile platinum loop is used to "dolly" across the medium through the spots inoculated. We have routinely inoculated two dishes with each swab. If a purulent nasal discharge is present, the medium is touched only once with the contaminated swab and preferably more than two dishes are inoculated.

The cough plates herein reported were taken in duplicate on only about half of the individuals tested. If duplicate plates had been taken with more regularity, our results with them would have been better.

* Read before the Laboratory Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 17, 1941.

The medium we have used is described in the footnote.* We do not wish to go into the merits of the various formulae described. Ours is essentially that used at the Serum Institute in Copenhagen. The inoculated plates are examined after 2, 3, or 4 days of incubation. Colonies are selected for staining by their pearl-like, shiny appearance when the media is tilted toward a desk lamp in a darkened room. All strains isolated were identified by the usual cultural methods. Agglutination tests were performed only occasionally.

pected in a public health unit where tests were made by a large number of individuals.

Table 1 summarizes the results of 210 comparative tests on 152 cases of pertussis seen during the past 17 months. The recorded cases which were bacteriologically negative were diagnosed on the basis of typical clinical findings. There is no doubt that we missed the diagnosis in some atypical cases of pertussis, for a number of bacteriologically proven cases were very mild or atypical. These latter cases of *Hemophilus pertussis* in-

TABLE 1

*A Comparison of Results with Cough Plates and Nasopharyngeal Swabs
210 Tests on 152 Cases in which Both Cough Plate and Swab Were Used*

Week of Disease	Both			Both		% + By Swab	% + By Plate	% + By Both
	Plate + Swab +	Plate + Swab + Swab -	Plate - Plate -	Plate - Swab -	Total			
1st	26	6	13	10	55	71	60	82
2nd	21	4	19	20	64	63	39	69
3rd	4	4	11	20	39	38	20	49
4th	7	3	3	9	22	45	45	58
5th	1	4	9	14
6th	6	6
7th	1	...	8	9
8th	1	1
Total	58	19	50	83	210	51	37	60

The nasopharyngeal swab and cough plates were taken by many different physicians and nurses often inexperienced in the procedures. The results therefore are by no means as satisfactory as might be obtained. The percentage of positive cough plates is definitely low as compared to results obtained by other workers.⁴⁻¹⁷ On the other hand, our results indicate what might be ex-

fection would have been missed clinically. Two cases of parapertussis have been encountered since this study began. (The authors have recently reviewed 10 cases of this latter infection¹⁸ seen during the past 4 years.)

Confirming the findings of Bradford and Slavin, Table 1 indicates that the nasopharyngeal swab yielded a higher percentage of positive tests than the cough plate. There were 50 tests in which the swab was positive and the plate negative as compared to 19 tests in which the swab was negative and the plate positive. The oft repeated observation that the earlier the cough plate is taken the more likely it will be positive, holds also for the nasopharyngeal swab.

* Preparation of medium: 500 gm. of peeled, sliced potatoes are cooked until soft in 1 liter of tap water containing 40 ml. of glycerine. The potato mixture is filtered through 4 thicknesses of cheesecloth; 125 ml. of filtrate are added to 12.5 gm. of agar, 5 gm. of neopeptone, and 375 ml. of 0.6 per cent sodium chloride in a 1 liter flask. The medium is sterilized for 30 minutes at 15 lb. pressure. For use, 250 ml. of defibrinated horse blood, slightly warmed, are added to the melted agar, cooled to approximately 45° C. About 20 thick plates of medium can be poured from this volume.

TABLE 2

*The Isolation of Hemophilus Pertussis by Cough Plate and Nasopharyngeal Swab
From 154 Cases of Pertussis*

(Some of these cases were not seen until the 5th or 6th week of cough)

	Both Plate + Swab +	Plate + Swab -	Swab + Plate -	Both Negative	Total	Total Swab +	Total Plate +
Number of Cases.....	60	15	38	41	154	98	75
% of Total Cases.....	39	10	25	27	73+	64	49
% of + Cases.....	53	13	34	87	66

It is also apparent that the use of both procedures is superior to the use of nasopharyngeal swabs alone.

Table 2 lists 154 cases studied and shows the percentage of cases (not the number of tests) which were positive. It should be mentioned that a few of these cases were not seen until the 5th or 6th week of cough. Sixty-four per cent of all cases were positive by swab at some time during their course, whereas 49 per cent were positive by plate. Eighty-seven per cent of the bacteriologically proven cases were positive by swab as compared to 66 per cent positive by plate.

In order to determine the viability of *Hemophilus pertussis* on the nasopharyngeal applicator, a considerable number of the applicators were placed in the electric refrigerator at 2° C. after they had been used to inoculate media. Of 41 applicators which were subsequently found to be positive on the initial streaking, 4 of 11 were again positive after 1 day of refrigeration, 3 of 19 were again positive after 2 days of refrigeration, and 2 of 10 were again positive after 3 days of refrigeration. It is apparent that *Hemophilus pertussis* may occasionally remain viable in mucus imbedded in cotton for 3 days at this temperature. It is also apparent that isolation of the organism is facilitated

by prompt inoculation on media and incubation.

Bradford and Slavin¹ noted that "sometimes the growth from the nasopharyngeal cultures was practically pure." We have also noted this. Very heavy growth is often encountered.

Further studies are being made to determine in particular, (1) the duration of carriage of *Hemophilus pertussis* in the nasopharynx during pertussis, and (2) the presence of *Hemophilus pertussis* in the nasopharynx of contacts.

The advantages of the nasopharyngeal swab technic as compared to the cough plate appear to be:

1. Higher percentage of positive cultures
2. Ease of transportation
3. Speed in obtaining the inoculum

The disadvantage to the method is the discomfort involved.

SUMMARY

The nasopharyngeal swab of Bradford and Slavin has been compared with the cough plate in the bacteriological diagnosis of pertussis. Two hundred and ten duplicate tests were made on 152 cases in all stages of the disease. *Hemophilus pertussis* was isolated more frequently by swab than by plate. The use of both procedures, however, was superior to the swab alone.

A Comparison of Methods for the Determination of Carbon Monoxide*

F. H. GOLDMAN, PH.D., F.A.P.H.A., AND A. D. BRANDT, Sc.D.

Chemist, and Passed Assistant Sanitary Engineer, Division of Industrial Hygiene, National Institute of Health, U. S. Public Health Service, Bethesda, Md.

THE 1940-1941 report of the A.P.H.A. Subcommittee on Chemical Methods in Air Analysis dealt with the determination of carbon monoxide. In the preparation of that report it became apparent that although certain methods were in constant use for the estimation of concentrations of carbon monoxide, very little had been done to evaluate them by comparison with other accepted methods when sampling the same environment. The investigation we are reporting here is an attempt to do this.

Six methods were included in this study. They are the iodine pentoxide method, the hopcalite indicator, the Hoolamite detector, palladium chloride ampoules, the British palladium chloride method, and the pyrotannic acid method.

The carbon monoxide test mixtures were prepared by generating the gas from formic and sulfuric acids. This carbon monoxide gas was then used to make up the carbon monoxide-air mixtures. An empty compressed air cylinder was used to store the carbon monoxide-air.

For the iodine pentoxide method, sampling was accomplished as follows:

The sampling tube A with both stopcocks open is totally immersed in the

water contained in cylinder B. The gas is then allowed to flow in through stopcock C, displacing the water in A. Stopcock C is now closed, the sampling tube A is raised to within about an inch of the surface of the water and then stopcock D is closed. This leaves the gas in the tube under a slight positive pressure. The tube is allowed to come to room temperature and the pressure within the tube is equalized before analysis by momentarily opening the stopcock.

FIGURE 1

The principle of this method is the reaction of carbon monoxide with iodine pentoxide to form iodine and carbon dioxide. The amount of iodine formed is then determined volumetrically.

The iodine pentoxide apparatus itself

* Read before the Industrial Hygiene Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 15, 1941.

has been slightly modified and the gas sample is analyzed as follows:

Air is drawn through the apparatus from the outside, passing through tube A which is filled with calcium chloride, tube B which contains ascarite, then through 3-way stopcock C, through tube D which contains ascarite, and E which contains magnesium perchlorate, through the liquid air trap F into the iodine pentoxide tube G, and through the iodine absorption tube H. I is a glass stopcock, J is a "T" which serves as a bleeder valve to regulate the rate of flow. The sample in K is drawn up through the stopcock C and continues through the apparatus in the same way as the air. Absorption tubes A, B, C, D, and E are sealed off at the top after being filled. The liquid air trap F was blown in the laboratory. The iodine pentoxide tube G is a Kraissl tube and the iodine is absorbed in a Bowen absorption bulb H.

TABLE 1

Concentration of CO % (by volume)	Sample Tube Capacity in ml.	Ml. of N/1,000 Arsenite Solution
0.01	1,000	1.8
0.03	1,000	5.4
0.10	1,000	18.0
0.25	300	13.0
0.40	150	11.0

It was found that about 75 ml. per minute was a good rate for the introduction of the sample into the iodine pentoxide apparatus, and that 15 minutes was sufficient for flushing. After the apparatus was conditioned by passing air through it and keeping the iodine pentoxide at 200° C., blanks on outside air gave no color with starch and potassium iodide even after running hour after hour and in between determinations.

No difference was observed whether or not the liquid air trap was used. This is of course only true of our syn-

FIGURE 2

Three sizes of sampling tubes were used—150, 300, and 1,000 ml. The volume of N/1,000 sodium thiosulfate or sodium arsenite solution needed for a single titration is given in Table 1.

These values are only approximations and serve to indicate the size of sampling tube that is necessary depending upon the carbon monoxide concentration.

thetic carbon monoxide—air and outside air samples.

Corrections for temperature and pressure make differences in the second decimal place, as for example, 0.250 per cent uncorrected against 0.277 per cent corrected.

The effect of varying concentrations of potassium iodide in the absorber was determined. We found that 20 ml.

solution when less than 25 ml. of solution are used.

These findings were also confirmed when thiosulfate was used instead of arsenite.

Just a word about starch solutions. We found soluble starch satisfactory, provided that it was freshly prepared. The use of a preservative such as toluol affects the titration of dilute iodine solutions and should be avoided. When starch solutions are made up with the addition of KI, the presence of KI will, of course, affect the value of the titration blank. The effect of adding the starch at the beginning or at the end of these titrations of N/1,000 solution with different amounts of KI was studied. It was found that in the presence of 2 per cent KI, the iodine values may be slightly higher if the starch is added immediately. It is better practice to wait until a few ml. of the end point before adding the starch as is usual.

The effect of bubbling CO₂ through the solution during the arsenite titration was also investigated. In the absence of CO₂, lower values were obtained for the iodine content. It appears, therefore, that CO₂ is necessary for this titration with thousandth

normal solutions and that losses due to volatilization of iodine during such procedure do not occur.

Table 2 is a summary of the results we obtained by the six methods employed. The iodine pentoxide results are regarded as the true values.

The hopcalite indicator values were obtained with the M.S.A. carbon monoxide detector. We used a number of hand driven and battery driven instruments. All canisters and cells were freshly prepared at the outset of these experiments. It is to be noted that this instrument gave very satisfactory results.

We have had considerable experience in servicing these instruments. Necessary repairs included changing canisters, refilling hopcalite cells, seeing that leads to the ammeter are not reversed, getting rid of leaks, cleaning out flowmeter fluid from connection to canister, tightening joints, recharging batteries, etc.

The Hoolamite detector gave consistently higher results at all carbon monoxide concentrations. At 0.01 per cent CO no color was obtained in twenty squeezes <0.05 per cent CO. If it is to be considered as a method at all it is only as a substitute for the canary

† Per cent blood saturation

bird. It probably was not designed to do much more than that.

The palladium chloride ampoules appear to be better than the Hoola-mite detector. Exposures should be timed at 10 minutes since longer exposures were found to darken the color.

The pyrotannic acid method gave a good average value at 0.01 per cent and 0.1 per cent CO. The value obtained at 0.05 per cent CO is twice as high as it should be. Two determinations were made and there were three observers for each determination. The air mixture was checked before and after with the M.S.A. CO indicator and found to be correct. The per cent saturation as read by different observers usually included three standards. This means that for concentrations where the value is very critical, say at 0.01 per cent CO the value obtained may be 100 per cent off, and constitute the difference between having a carbon monoxide hazard and not having one.

The British test paper method, which like the ampoule detector is a palladium chloride method, gave fairly good re-

sults. In the higher concentrations the values became too great. It was found that if the papers were read when wet and standing a little off at a distance, very good comparisons could be made. However, the method is a slow one and requires a considerable number of values for averaging. Reading Table 2 across, we see that at 0.3 per cent CO the iodine pentoxide method is the only reliable method to use. The other values are too high, but all read on the safe side.

At 0.1 per cent CO the hopcalite indicator gives a very good result as do also the pyrotannic and British palladium chloride methods.

At 0.05 per cent CO the hopcalite indicator is the most accurate. The British palladium chloride method also gives a good result, while the others give figures about twice as high.

At 0.01 per cent CO the hopcalite indicator, pyrotannic acid method and British method give good results. All in all, if we consider the time factor and the number of determinations, the hopcalite indicator gives by far the best performance.

Blood Lead Determinations as a Health Department Laboratory Service*

EMANUEL KAPLAN, Sc.D., AND JOHN M. McDONALD, M.D., D.P.H.

Chief, Division of Chemistry, Bureau of Laboratories; and Director, Bureau of Occupational Diseases, City Health Department, Baltimore, Md.

THE Baltimore City Health Department first became interested in lead poisoning in 1929 in an investigation of several cases of industrial lead poisoning. This interest was broadened in 1932 when an outbreak of 40 non-fatal cases of lead poisoning occurred mostly in children as a result of the inhalation of fumes and dust arising from the use of discarded storage battery casings for fuel.¹ Subsequently, for a period of more than four years all cases of lead poisoning which came to the attention of the Health Department were routinely investigated in order to ascertain if possible the source of the lead exposure in both adults and children. Early in 1935, at the request of Dr. Edwards A. Park, Pediatrician-in-Chief at the Johns Hopkins Hospital, the Bureau of Laboratories provided facilities for the quantitative estimation of lead in blood in cases of suspected plumbism. These facilities were soon expanded into a routine service. The usefulness of the quantitative blood lead analysis as an index of abnormal lead absorption had already been demonstrated at that time by the extensive studies of Blumberg and Scott at the Johns Hopkins Hospital² as well as by other investigators.^{3, 4} Subsequent investigations have further confirmed the value of this

analysis in providing evidence of lead absorption in cases of suspected lead intoxication.⁵⁻¹⁴

Since July, 1935, we have routinely examined more than 1,400 specimens of blood from over 1,000 individuals. The blood lead service has been used by more than 20 local hospitals and by more than 80 private physicians. At the present time approximately 30 specimens of blood are examined each month. No charge is made for this work. It is the purpose of the present report to describe this unique laboratory service and to call attention to the valuable assistance which it has given to our Division of Industrial Hygiene and Bureau of Occupational Diseases in locating lead hazards and in evaluating the extent of lead poisoning in the community.

COLLECTION OF SPECIMENS

Ten gram samples of whole clotted blood are used in these examinations. In order to minimize contamination, only specimens submitted in prepared containers known as "blood lead outfits" (Figure 1) are accepted for analysis. The outfit consists of a lead-free glass test tube (17 mm. x 91 mm.) stoppered with a clean new XXXX quality Armstrong cork. The tube is first cleaned, then rinsed with nitric acid and lead-free water, and dried. The tube, together with an identification card requesting information concerning the

* Read before the Industrial Hygiene Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 15, 1941.

FIGURE 1

name, address, age, sex, color, occupation, and length of exposure to lead of the patient is packed in a distinctive cardboard box bearing the "blood lead outfit" label. Directions for collecting the blood specimen are printed on the reverse side of the card. Recently, the outfit was further improved by the provision of a sterile, lead-free, rustless, 19 gauge, Petroff needle (Becton Dickinson, Number 497N) contained in a small paper envelope. The needle is suitable for adult use only and eliminates the need for a syringe. The cost to us of the blood lead outfit including the needle is $7\frac{1}{2}$ cents. The outfits are distributed by the Bureau of Laboratories to the local medical profession and hospitals in the same manner as outfits regularly provided for the collection of specimens in cases of infectious diseases.

METHOD OF ANALYSIS

It is now well established that traces of lead are normally present in the blood. The difference between normal and abnormal amounts of lead in circulating blood is a quantitative and not a qualitative distinction and requires the use of highly sensitive and accurate means of lead estimation. In this work the modification of the dithizone method described by Wilkins, Willoughby, *et al.*^{5, 15} was used. The method was further modified to include

the neutral wedge photometer in accordance with the technic of Clifford and Wichmann.¹⁶

Meticulous supervision is required. The method is practical only when a sufficient volume of samples is anticipated. In our laboratory, reagents and equipment are available for the simultaneous examination of 6 specimens. This equipment necessitated an outlay over a period of 4 years of more than \$400. However, the average cost of a single examination is estimated at about 25 cents. The figure given does not include the cost of labor. When analyses are made in multiple, the average time required of the analyst for a single analysis is slightly more than 1 hour.

REPORTING OF RESULTS

Blood lead concentrations are reported as mg. lead per 100 gm. of blood. Recently, for convenience, the following summary of the interpretation of the blood lead value was printed on the report form which is mailed to the physician.

INTERPRETATION OF RESULTS

It is now recognized that in the general population the average lead content of the blood is about 0.03 mg. per 100 gm. In persons with no history of exposure to lead, the blood lead level may range as high as 0.05 to 0.06 mg. per 100 gm. of blood. Higher blood lead values are evidence of abnormal absorption of lead and suggest the relative severity of the recent lead exposure.

Lead absorption is not synonymous with lead poisoning. Experience has demonstrated that individuals in industrial lead exposures may have abnormal blood lead levels with no accompanying symptomatology. A high blood lead level is not, of itself, diagnostic of lead poisoning but must be correlated with other findings, both clinical and laboratory, as well as with a history of definite exposure to lead.

No direct correlation exists between the degree of elevation of the blood lead value and the severity of the symptoms. It should be further noted that in convalescence from lead poisoning the blood lead value may remain in the abnormal range for a considerable period after symptoms have disappeared.

TOTAL (750)	126*	82	74	291	177

* Mean normal value 0.031 with standard deviation ± 0.012 .

If the findings in this report indicate a doubtful result or an abnormal absorption of lead, an additional specimen of blood and also a specimen of urine should be examined. Because of the time and expense involved in making these analyses, physicians must communicate directly with the Director, Bureau of Laboratories, in order to make arrangements for repeat tests.

This interpretation is based on the available literature cited in the above references as well as upon our own experience.

SUMMARY OF BLOOD LEAD FINDINGS

At the outset the laboratory service was intended merely to provide practitioners with an aid in the diagnosis of lead poisoning particularly in cases involving infants and young children. The coöperation of the hospitals and private physicians who made use of the laboratory service was solicited in order to make available the clinical histories of those individuals whose bloods had been examined for lead. This investi-

gative work was expanded after the creation of the Bureau of Occupational Diseases in the Baltimore City Health Department in 1936. In this way, an excellent source of information was provided as to the occurrence of both industrial and nonindustrial lead poisoning in the city. In addition a study of the case histories permitted a correlation of the chemical blood lead determination with the clinical signs and symptoms, the history of exposure, and the final diagnosis made in each instance. Case histories of 624 individuals (373 adults and 251 children) have thus far been examined. A distribution of the blood lead values of this group in relation to the clinical diagnoses made is shown in Table 1.

Initial blood lead values only are recorded in this table; values obtained in convalescence or after treatment are not shown. The table also includes a series of specimens from 31 adults and 95 children (126 in all) with no history

of industrial or other exposure to lead. These specimens were obtained through the coöperation of the local infectious disease hospital. The blood lead values in this "normal" group were not significantly different for the adults and children. Since these individuals were not "normal" with respect to health, it is conceivable that metabolic disturbances associated with infectious disease may have slightly elevated the blood lead values of some members of the series.

In the group diagnosed as clinical lead poisoning our data include 82 adults, all but one of whom contracted lead poisoning in the course of their occupations; and 74 children of an average age of $2\frac{1}{2}$ years, practically all of whom had a history of pica associated with the chewing of objects painted with lead containing paints. In many of the children's cases, analyses were made of paint scrapings to confirm the source of lead. Specimens from all but one of the 251 children were submitted from hospitals. On the other hand, specimens from 30 per cent of the adults were submitted by private physicians.

In plumbism, the most commonly occurring blood lead values in both adults and children was in the range of 0.1 to 0.2 mg. per 100 gm. of blood. Values in excess of 0.2 mg. occurred far more frequently in affected children than in adults.

The group tabulated as "negative clinical diagnosis" consists of individuals whose clinical histories did not show a diagnosis of lead poisoning. Many of the children in this group had a history of pica. Almost all of the adults were engaged in occupations wherein some abnormal absorption of lead might be suspected. Those adults in this category who showed blood lead values in excess of 0.07 mg. were definite examples of asymptomatic lead absorption. These men were engaged

in such occupations as the manufacture of lead paint pigments, the manufacture of lead arsenate, scrap lead reclamation, and lead burning.

USEFULNESS OF THE BLOOD LEAD SERVICE AS A HEALTH DEPARTMENT METHOD

The local medical profession is accustomed to asking for a blood lead determination by the Baltimore City Health Department in cases of suspected lead poisoning encountered in their practice. A copy of the result of each analysis is forwarded to the Bureau of Occupational Diseases for investigation. In this way the majority of the actual lead hazards in local industry have been defined and numerous corrections of lead exposures were obtained.

With the reports from the blood lead service as a clue, numerous instances have occurred in the past 6 years wherein outbreaks of industrial lead poisoning were immediately called to the attention of the Bureau of Occupational Diseases and the Division of Industrial Hygiene. An excellent example which has already been cited¹⁷ related to an incident involving several cases of lead poisoning in a manufacturing plant. A cross-connection in plumbing permitted a solution of lead compound to enter the water supply of a drinking fountain in the plant. Numerous other incidents have occurred which involve such diverse occupations as the manufacture of lead arsenate, the manufacture of lead paint pigments, acetylene torch burning in shipbreaking, enamelling with lead-containing frit and the cleaning of tanks which had been used for the storage of leaded gasoline.

In recent years, largely as a result of studies associated with a follow-up of the blood lead laboratory service, it has been possible for the Baltimore City Health Department to acquire relatively accurate information concern-

TABLE 2

Reporting of Non-fatal Lead Poisoning in Baltimore City, 1931-1940

Year	Total Non-Fatal Cases	Cases Reported		Cases Not Reported But Ascertained Through Follow-up of Laboratory Service

1937	24	16	8
1938	11	2	..	2	7
1939	18	11	7
1940	26	3	..	18	5
TOTAL	172	23	45	63	41

ing the incidence of lead poisoning in the community.¹⁸ During the past 10 years, all of the known cases of fatal lead poisoning (49 children and 7 adults) were reported to the Bureau of Vital Statistics. However, there has been little tendency to report cases of non-fatal lead poisoning. This fact is strikingly demonstrated in Table 2.

The increased incidence of reported lead poisoning in 1932 is due to the storage battery outbreak mentioned earlier.¹ Beginning in 1935, it will be noted that the Health Department became aware of a large number of unreported cases of non-fatal lead poisoning. This resulted directly from the follow-up of the laboratory service. Only those cases are listed in which an investigation with regard to the history of exposure, signs, symptoms, and laboratory examination furnished evidence to substantiate the diagnosis of lead poisoning.

SUMMARY

A description has been given of a blood lead laboratory service which the Bureau of Laboratories of the Baltimore City Health Department has made available to the physicians and

hospitals of Baltimore during the past 6 years. The service has proved invaluable to the Division of Industrial Hygiene and the Bureau of Occupational Diseases in locating lead hazards and in evaluating the extent of both industrial and nonindustrial lead poisoning in the community.

The House Fly as a Vector of Food Poisoning Organisms in Food Producing Establishments*

MORRIS OSTROLENK AND HENRY WELCH, PH.D.,
F.A.P.H.A.

U. S. Food and Drug Administration, Federal Security Agency, Division of Bacteriology, Washington, D. C.

THE house fly (*Musca domestica*) has been incriminated as a vector of food poisoning bacteria on many occasions. Classical epidemics of food-borne infections such as the typhoid epidemics among soldiers during the Boer¹ and Spanish-American² wars, each of which involved more than 20,000 cases, and the widespread cases of diarrhea in Southend-on-Sea³ in 1901 were traced to the contamination of food by flies. These and numerous other food poisoning epidemics, in which flies were thought to have been responsible for infecting food supplies, have led many investigators to study the potentialities of house flies as carriers of pathogenic bacteria. A more complete review of the literature and the results of some preliminary experimental data have been reported in a previous publication⁴ in which it was shown that flies are capable of depositing on food by defecation or regurgitation countless numbers of bacteria, and further that the bacterial flora deposited is largely determined by the nature of the material on which the flies feed. Flies infected with *Salmonella enteritidis* and allowed to come in contact with sterile pecan meats deposited these

pathogens in large numbers on the pecans left exposed for only 15 minutes.

Since the publication of those data several hundred flies trapped in and around crabmeat producing establishments were found to contain total bacterial counts of 750 million and as many as one million *Escherichia coli* per fly.

In the present study experiments have been conducted with flies using *Salmonella enteritidis* as the test organism to determine the ability of flies to infect other flies, the longevity of the test organism in flies, the transmission of *Salmonella enteritidis* from infected flies to mice, and the ability and extent to which uninfected flies would become vectors of the test organism when exposed to infected mice. Some studies were also carried out on the survival of *Salmonella enteritidis* during metamorphosis from eggs to adult flies.

EXPERIMENTAL WORK

The methods employed in rearing flies have been previously reported,⁴ but briefly are as follows: Eggs are collected on milk- and water-soaked cotton and are suspended in physiological salt solution. This suspension of eggs is poured on the surface of a bran-alfalfa-leaf-meal medium into which is poured and kneaded a mixture

* Read at a Joint Session of the Engineering and Food and Nutrition Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 15, 1941.

consisting of a commercial malt syrup, yeast suspension, and water. Maggots may be allowed to pupate in the top dried-out layers of this synthetic medium or in a pan of sawdust. The emerging flies are trapped in cages. For control purposes, the synthetic mash, developing maggots, and adult flies were examined for *Salmonella enteritidis*.

Since in the following experiments, with *Salmonella enteritidis* as the test organism, it was desirable to reduce surface contamination of the flies to a minimum, two methods of feeding were used. In the first of these a small cylindrical glass cup was filled to within 2 to 2.5 mm. of the top with infected food (10 ml. of an 18 hour broth culture of *Salmonella enteritidis* in equal parts of milk and water). Over this was placed a fine mesh screen. It was intended in this manner to prevent the flies from standing on or falling into the liquid food. In feeding, the fly forced its proboscis through the wire mesh. This method was not as successful as the second method in which a piece of evenly cut blotting paper was placed on a cylindrical feeding cup filled with

the liquid food and this cup, full of food, then inverted over a second empty cup, the blotting paper acting as a separator (Figure 1). If the blotting paper is cut slightly smaller in diameter than the outside diameter of the cup, none of the soaked-up portion of the blotting paper is exposed to cause surface contamination of the flies when they are feeding. Drinking water is provided by covering a small bottle of water with a piece of filter or blotting paper and inverting it over a watchglass, as shown in Figure 1.

TRANSFER OF *SALMONELLA ENTERITIDIS* FROM FLIES TO FLIES

Using the second method, approximately 100 flies were fed for 24 hours on milk and water infected with *Salmonella enteritidis*. At the end of the 24 hour period 10 flies were trapped and anesthetized with ether. One wing of each was clipped and the flies placed in a sterile cage with approximately 100 uninfected, unmarked flies. The flies making up this population were fed fresh uninfected milk and water daily. Each day all dead flies and from 10 to 20 live unmarked flies were removed

FIGURE 1—Feeding and Watering Flies: Pieces of filter or blotting paper are placed between the feeding cups and between the water bottle and the watchglass.

and examined by washing for 10 minutes in a mixture of 1 per cent sodium hydroxide, 1 per cent aerazol and 5 per cent formaldehyde, followed by washing from three to five times with nutrient broth. The washed flies were then ground in a sterile mortar and the residue examined for the presence

10 unmarked flies from the second group.

All swabbings from cage surfaces, washings from flies, and residue of ground flies were inoculated into tetrathionate broth and then streaked on bismuth sulfite agar for study. Suspicious colonies were fished and ex-

of *Salmonella enteritidis*. The nutrient broth washings, the food, water, and swabbings of the wood, wire, and glass surfaces of the cage were likewise examined. At the end of 4 days 10 unmarked flies from this first group were anesthetized, marked by clipping one wing, and placed in a sterile cage with a fresh group of 100 uninfected flies. This second group of flies was fed daily on uncontaminated milk and water. All dead flies and from 10 to 20 live unmarked flies were removed from this group daily and, as in the first group, examinations were made of surface washings and macerated flies, the food, water, and of the swabbings of the wood, wire, and glass surfaces of the cage. At the end of an additional 4 days a third population of flies was established in a similar manner, using

aminated. All organisms were identified both biochemically and serologically. The results are shown in Table 1, where it will be noted that surface washings of flies, after chemical treatment, failed to contain *Salmonella enteritidis*. The residue from unmarked macerated flies, taken as an index of intestinal content, was found to contain the test organism in all three populations of flies, thus indicating transfer of *Salmonella enteritidis* from infected to uninfected flies in all three instances. *Salmonella enteritidis* was also recovered from the fly food, water, and cage surfaces in each of the fly populations established. These experiments were repeated twice with similar results. However, in repeating, both methods of feeding described above were used and daily transfers of known infected flies to un-

infected populations were made rather than transfers at 4 day intervals.

LONGEVITY OF *SALMONELLA ENTERITIDIS* IN FLIES

To determine the longevity of *Salmonella enteritidis* in flies and the period of time these test organisms would be deposited by defecation, several hundred flies were fed *Salmonella enteritidis* for 24 hours, as described in the previous experiment, after which they were placed in a sterile cage and fed sterile milk and water daily. Several pieces of orange or banana peel were also placed on the floor of the cage daily. At the end of the second day 10 flies were removed for examination, and the remainder were transferred to a sterile cage. The flies removed for study were treated chemically to remove surface organisms and then macerated and tested for presence of *Salmonella enteritidis*. The surfaces of the cage from which the flies were removed and the food and water were also examined for this organism. On the 4th, 5th, 6th, 7th, 10th, 17th, and 20th days this performance was repeated, i.e., on each of these days the flies were examined for *Salmonella enteritidis* and the remaining flies transferred to a sterile cage. Following each

transfer the old cage was examined for contamination with *Salmonella enteritidis*, as were the water and food it contained.

Salmonella enteritidis was isolated from the flies on each day examined except the 7th and 17th days. Sporadic recovery of the test organism from the fruit peel, fly food, and water and from cage surfaces occurred throughout the 20 days (Table 2). Although additional flies with which to continue this experiment were not available, the results of related experiments indicated that the test organism could survive for the entire duration of the life of the fly, approximately 4 weeks.

TRANSMISSION OF *SALMONELLA ENTERITIDIS* FROM FLIES TO MICE AND FROM MICE TO FLIES

In previous publications^{5, 6} it was shown that extremely small inocula (*per os*) of the strain of *Salmonella enteritidis* used in these experiments were necessary to bring about infection and subsequent excretion of the organism in both rats and mice. It was found that approximately seven organisms fed by stomach tube to mice caused a high incidence of fatalities in 13 days or less. To determine the ability of flies to transmit *Salmonella*

FIGURE 2—*Mice and Flies Caged Together*: The screen bottom of the mouse cage is on an open pan to allow for the collection of pellets.

enteritidis to mice or to become vectors of the organism in the presence of infected mice, the following experiments were conducted.

A one day old population of flies was fed for 24 hours on a mixture of an 18 hour broth culture of the test organism in milk and water, after which the flies were placed in a large sterile fly cage containing a small wire mouse cage in which were 6 uninfected mice (Figure 2). The mice were watered and fed daily, and the flies received fresh uncontaminated milk and water soaked up in absorbent cotton in an open Petri dish. In addition, each day the small half of a Petri dish with the open side down and several pieces of fruit peel were placed on the floor of the cage. At the end of the 4th, 12th, and 18th days all dead flies and from 5 to 14 live flies were removed for examination. The food and water of both the mice and flies, the fruit peel, the exposed Petri dish, the mouse pellets which had fallen out of the mouse cage onto the floor of the fly cage, and

those pellets in the pan of the mouse cage were also examined. To avoid direct contamination by flies of exposed pellets on the floors of the cages, one or more pellets were forced from the intestinal tract of each of the 6 mice on each day examinations were made.

At the conclusion of this experiment, to determine whether transfer of *Salmonella enteritidis* from infected mice to flies was possible, the mouse cage and the feeding and watering cups were first sterilized by autoclaving. The fly cage was thoroughly washed with 5 per cent phenol, allowed to air dry, and a fresh uninfected population of flies placed in it. The sterilized mouse cage containing the 6 mice of the previous experiment, 4 of which were demonstrated to be infected with *Salmonella enteritidis*, was placed in the fly cage. At 1 week intervals for 3 weeks the food and water of both mice and flies, the fruit peel, the exposed Petri dish, and mouse pellets were examined for *Salmonella enteritidis*.

In the first of these experiments, in

1. Three hundred infected flies placed in a sterile cage with 6 normal mice and examinations made as indicated.

2. The infected mice placed in a sterile cage with 300 uninfected flies.

3. Washings of chemically treated flies.

4. Ground up flies after chemical treatment to remove surface organisms.

+ *Salmonella enteritidis* isolated.

0 *Salmonella* not isolated

which infected flies were caged with uninfected mice, as will be noted in Table 3, the test organism was isolated from the fruit peel, fly food, naturally expelled mouse pellets, and Petri dish on the 4th, 12th, and 18th days, while the fly water, mouse food and macerated flies after chemical treatment contained *Salmonella enteritidis* on 2 of the 3 test periods. The mouse water was examined only once and found to contain the test organism. Mouse pellets forcibly expelled were found to contain *Salmonella enteritidis* on each of the test periods from 4 of the 6 mice used.

In the second portion of these experiments, in which infected mice were caged with uninfected flies, examinations were made of the fruit peel, fly food and water, Petri dish, mouse food and water, and mouse pellets at 1 week intervals for 3 weeks. The test or-

ganism was isolated at least once from each of these materials. Macerated flies, after chemical treatment, contained *Salmonella enteritidis* at the end of the 1st week and continued to harbor the test organism for the duration of the experiment. At the end of the 1st week 5 of the 6 mice were shedding the test organism in the feces, as shown by examination of pellets forcibly expelled, whereas only 4 mice were positive for *Salmonella enteritidis* at the end of the 2nd week, and only 2 were positive at the end of the 3rd week. One of the 2 mice, shedding the test organism at the end of the 3rd week in the second half of these experiments, died on the 41st day. *Salmonella enteritidis* was isolated from the liver and kidney. Another mouse, shedding the test organism at the end of the 2nd week but not at the end of the 3rd week, died after the conclusion of this.

experiment (59th day). No positive cultural tests for *Salmonella enteritidis* were obtained on autopsy.

SURVIVAL OF *SALMONELLA ENTERITIDIS*
DURING METAMORPHOSIS OF
HOUSE FLY

To determine the ability of *Salmonella enteritidis* to survive during metamorphosis of the house fly, the following experiments were conducted. Fly eggs were collected on milk- and water-soaked cotton. The eggs were removed with the aid of a penknife and suspended in physiological salt solution in order to break up the small clumps. Settled eggs were resuspended in fresh physiological salt solution and again allowed to settle. In this manner, using only settled eggs, the eggs were washed 5 times. After the final washing the eggs were resuspended in physiological salt solution and poured on the surface of the bran-alfalfa-leaf-meal medium which had previously been sterilized by autoclaving. Immediately following this, 10 ml. of an 18 hour broth culture of *Salmonella enteritidis* was poured over the surface of the mash. The battery jar of infected mash and eggs, covered with sterile cotton-covered cheesecloth, was allowed to stand until full-grown maggots had developed. Approximately 500 maggots were removed, washed with physiological salt solution several times, and then treated with sodium hydroxide, aerazol and formaldehyde, as described previously, followed by direct washing in tetrathionate broth. Approximately one-half the treated maggots were then ground in a sterile mortar and examined for the test organism, as were the washings before chemical treatment and specimens of the infected mash. The balance of the treated maggots were placed on sterile sawdust in a Petri dish to pupate, and emerging flies were trapped and examined for *Salmonella enteritidis*.

The test organism was recovered from the infected mash and from the washings of the maggots before chemical treatment. Although chemical treatment failed to sterilize the surface of the maggots, all Gram-negative forms were destroyed and *Salmonella enteritidis* was not recovered from washings of maggots following this type of treatment. The test organism was recovered, however, from the residue of ground maggots after such chemical treatment, and *Salmonella enteritidis* was isolated from the residue of ground flies, trapped as they emerged from the pupal case. The remarkable resistance of maggots to rigorous chemical treatment, wherein they were exposed to a mixture of 1 per cent sodium hydroxide, 1 per cent aerazol, and 5 per cent formaldehyde for 30 minutes, is exemplified by their ability to emerge from the pupal stage following such treatment.

DISCUSSION

The known habits of flies make them important vectors in and around food establishments of bacteria of all kinds with which these pests may come in contact. In our preliminary studies of this problem we were able to demonstrate that flies are an extremely potent source of pollution organisms, particularly in those food plants where little attention is paid to sanitation and where the food is prepared for the consumer without a final treatment to destroy these organisms.

In extending our studies to include an organism of the food poisoning type, it has been demonstrated that *Salmonella enteritidis* may be transmitted with ease and rapidity through several populations of flies, and that all surfaces with which the infected fly comes in contact become potential sources of reinfection for other insects. Our studies show that not only does the fly carry the organism on its outside

surfaces, but also in its digestive tract, since the infected, macerated insect contains large numbers of the test organism while the organism cannot be isolated from the chemically treated, washed fly. The ease of transfer of food poisoning organisms from fly to fly and the fact that such organisms survive in the fly for practically the entire life span of these insects lends added significance to their potentialities as sources of food poisoning outbreaks. In contrast to the significance of rats and mice as vectors of food poisoning organisms, house flies appear to us to be much more important in food plant sanitation.

The transfer of food poisoning bacteria by flies to mice and the subsequent retransfer from infected mice to flies, with apparent ease of transmission of infection, mark these insects as potential health hazards wherever food that is to be eaten raw is being prepared. Whereas it was found^{5,6} that the strain of *Salmonella enteritidis* used in these experiments produced a high incidence of fatalities in mice in 13 days or less, only 2 of the 6 mice infected through flies died, 1 on the 41st day and the other on the 59th day after infection. Although the strain used has been shown to be highly fatal for both rats and mice when fed by stomach tube, in the present studies the rodents survived for considerably longer periods of time. It is not possible to say whether this may be associated with a loss of virulence of this organism or from other factors. However, it is worthy of mention that in some dissociation studies not yet completed both coliform bacteria and *Salmonella enteritidis* produced a number of variants on passage through flies, and this may have some bearing on the ability of those mice infected through flies to survive infection.

The data obtained on the survival of *Salmonella enteritidis* during meta-

morphosis of the house fly indicate that flies breeding in infected material can give rise to infected maggots, pupae, and adults. Although the potential danger of infection of fly breeding grounds may be remote, the possibility of its occurrence would constitute a source of grave danger, particularly during the summer months when fly breeding is at its peak and climatic conditions are most favorable for bacterial development. The removal of waste and refuse from the vicinity of food producing plants, adequate protection by screening to prevent fly contact with food, and the elimination of flies from such establishments are essential in plant sanitation.

SUMMARY—CONCLUSIONS

Flies fed on food infected with *Salmonella enteritidis* are capable of infecting other flies as well as the food, water, and miscellaneous surfaces with which they come into contact.

Salmonella enteritidis apparently survives in the fly for the duration of the life of the fly, approximately 4 weeks.

Transfer of *Salmonella enteritidis* infection from infected flies to mice and the retransfer of infection from infected mice to flies was successfully carried out.

Fly eggs planted in mash infected with *Salmonella enteritidis* resulted in infected maggots, pupae, and adults.

Training of Medical Personnel in Syphilis Control*

WILLIAM W. FRYE, PH.D., M.D., R. H. KAMPMEIER, M.D.,
AND A. E. KELLER, M.D.

Vanderbilt University School of Medicine, Nashville, Tenn.

DURING the latter half of 1937 a 4 weeks' postgraduate course in syphilis control was organized in the Vanderbilt University School of Medicine. The syphilis clinic was organized as a special clinic in the Department of Medicine during 1926, and was for a number of years concerned only with the instruction of undergraduate students. The expansion of the clinic activities for postgraduate instruction was made possible by funds allotted by the U. S. Public Health Service. The first course was given in January, 1938, and was repeated 6 times each year prior to July 1, 1941.

The need for postgraduate training was the outcome of rapid expansion of the syphilis control program and lack of prepared personnel to direct the various activities which were being organized in the respective states. The increase in number of syphilis clinics in the United States during the past ten years is shown in Table 1. In 1935 there were 656 clinics reporting from the various states. By 1940 the number was over three times as great. This rapid expansion was made possible by funds made available to the individual states from appropriations for venereal disease con-

trol after passage of the Social Security Act in 1935 and the Venereal Disease Control Act in 1938.

The course in syphilis control was planned especially for the training of county health officers, private physicians coöperating with local health departments and public health nurses. The chief objectives were to provide an opportunity for a period of intensive instruction in diagnostic and therapeutic procedures, epidemiology, and the broader public health aspects of syphilis control. The advisability of having a 4 week period of instruction was questioned when the course was first organized. It seemed advisable, therefore, to evaluate the 3½ years' experience with the short intensive course of instruction.

CLINICAL ORGANIZATION AND OUTLINE OF COURSE

A detailed description of the organization of the course was published by Kampmeier and Clark in 1939. The syphilis clinic is attended each week by about 350 patients, both white and colored, in four clinic sessions, one of which is a night clinic. The organization of the clinic is shown in Diagram 1.

The clinic staff is made up of 3 full-time members of the Department of Medicine, a visiting dermatologist, 2 full-time members of the Department of Preventive Medicine and Public Health, and 2 social workers especially trained

* From the Department of Preventive Medicine and Public Health and the Department of Medicine aided by funds allotted by the United States Public Health Service.

Read before the Southern Branch, American Public Health Association at the Tenth Annual Meeting in St. Louis, Mo., November 11, 1941.

in contact investigation and follow-up of patients under treatment.

SCHEDULE OF HOURS AND SUBJECT MATTER

The distribution of the 160 scheduled hours for the course, according to subject matter, is shown in Table 2.

The clinic sessions of which there are four take up a total of 44 hours. Each student spends the first 2 hours in the clinic with a member of the staff and individual cases already under treatment are seen. Problems in the man-

agement of each patient are discussed. The students also have an opportunity to discuss these patients with reference to epidemiology and follow-up based on field experience. Education of patients and methods of obtaining names of contacts are demonstrated. During the last hour of each clinic session new patients are presented to the entire student group. The history of each patient is reviewed, the diagnosis discussed, and darkfield technic demonstrated. In this way every new patient admitted to the clinic is seen by the

POSTGRADUATE INSTRUCTION IN SYPHILIS CLINIC

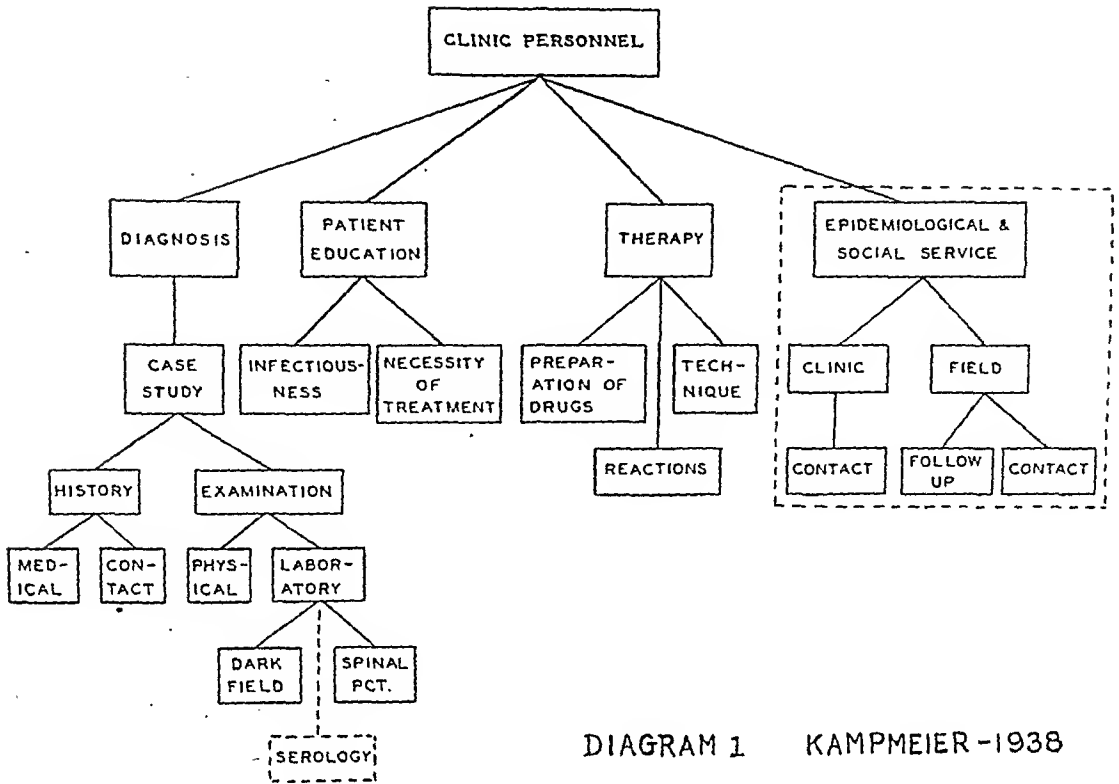

DIAGRAM 1 KAMPMEIER-1938

entire group and all phases of management of these patients are observed.

About one-third of the time is assigned to group instruction in the form of lectures and seminars. Lectures are given on the clinical and epidemiologic aspects of syphilis. These are supplemented by assigned readings in the library. These readings are discussed in seminars conducted by a member of the full-time staff. During the first 2 weeks the procedures used in obtaining names of contacts and methods employed in the field are discussed. During this 2 week period each student is required to make field trips with the epidemiologist and social worker to visit contacts and learn methods of approach in getting contacts to come in for examination. During the last 2 weeks each student is assigned two or more contacts of acute or early cases

of syphilis which he must visit and get in for examination without assistance.

Congenital syphilis is discussed by a member of the full-time pediatric staff in the syphilis clinic conducted in the outpatient pediatric service.

The students are also given opportunity to spend some time on various phases of epidemiology or clinical syphilis in which they may be especially interested. In some instances trainees have conducted special clinical studies, as well as participating in the clinic, for a period of 3 or more months.

Postgraduate nurses attend the lectures and seminars, and are given the same course of instruction except that they spend their time in the clinic with the social workers. They attend patient demonstrations at the close of each clinic session, when new cases are presented and discussed. At the close of the 4 weeks' session they are assigned to the

social workers for another 4 weeks' period of field training. Social problems are taken up and they are assigned cases in the clinic for follow-up. Also additional contacts are assigned to be visited and brought to the clinic or directed to private physicians or to other clinics for examination.

DISTRIBUTION AND TYPE OF MEDICAL PERSONNEL

Six physicians and 2 nurses are admitted to each 4 weeks' course. Since the postgraduate instruction was organized (3½ years ago) 115 physicians and 33 public health nurses have completed the course. In the group of 115 postgraduate physicians, 54 were health officers and 61 were practising physicians who were cooperating with their local health departments in the syphilis control program. The nurses were previously engaged in some type of public health work, either in a county or city, or as supervisors in the state or county public health nursing program.

A geographic distribution of trainees is shown in Table 3.

The physicians and nurses have come from 11 states for postgraduate instruction in syphilis control. Kansas has furnished 2 nurses; California, Okla-

homa, and Virginia have each sent only physicians. Mississippi has furnished 68 of the 115 physicians and 10 of the 33 nurses. It is also interesting to note that 53 of the 68 physicians from Mississippi were private practitioners participating with their local health departments in the syphilis control program. Only 3 other states have sent private physicians: Oklahoma 4, Missouri 3, and Texas 1. There have also been more health officers from Mississippi than any other state, 15 in all. California has had 9 and Missouri 8 health officers who have completed the course. Mississippi, Oklahoma, Missouri, and Texas have had both health officers and private physicians. The remainder of the states sending physicians have sent only full-time health officers.

Five states, Mississippi, Missouri, Texas, Tennessee, and Alabama have sent 27 of the 33 nurses who have completed the full 8 week course of training.

INFORMATION OBTAINED BY QUESTIONNAIRE

In order to get some evaluation of the short but intensive period of training, questionnaires were mailed to all

postgraduate physicians and nurses. Forty health officers, 30 private physicians coöperating with health departments, and 22 nurses answered the questionnaire. Table 4 shows the type of teaching material and methods preferred by the 70 physicians. Material presented in the lectures was rated first by the highest percentage of physicians. Working with the staff in the clinic and

case demonstrations at the end of each clinic period were also given a high rating. It is interesting to note that epidemiology was rated first by only 1 and second by 4 of the physicians. In many instances the statement was made in the questionnaire that they realized that epidemiology was the most important part of the syphilis control program, yet they personally did not

like to do contact investigation or follow-up work.

Table 5 gives some general points with reference to management of patients with syphilis. It is noted that 50 per cent of the private physicians stated that they had made radical changes in their method of treatment. A high percentage of both health officers and private physicians were either doing or having darkfield examinations done and spinal fluids examined. It is also encouraging to find that only 1 health officer and 1 private physician were not getting names of contacts of acute cases. The health officer stated that this was not being done because of lack of clinic personnel.

CLINIC ACTIVITIES OF HEALTH OFFICERS AND PRIVATE PHYSICIANS

Table 6 shows the number of clinics the 39 health officers conducted or had under their direct supervision each week. These figures show an average of 5 clinics per week. In the 196 syphilis clinics conducted by health officers the average number of patients treated per week was 20,000. Two of the health officers stated that they were operating clinics in which 2,000 patients were treated per week. Information as to the number of physicians participating in the 196 clinics per week was not obtained.

Table 7 shows that the private physicians participating in the clinics under health department supervision assist in one or two clinics and spend an average of from 3 to 4 hours each week in the

clinics. Each of these private physicians treats an average of approximately 100 patients per week.

It was also significant that practising physicians answering the questionnaire stated that they were assisting in every way possible to stimulate interest in venereal disease control in their particular locality and among the members of the medical profession. Many stated that they were getting names of contacts from private patients and that these names were turned over to the health department for investigation.

ACTIVITIES OF THE PUBLIC HEALTH NURSES

Twenty-two of the 33 nurses who had completed the course answered the questionnaire. Seven of the 22 were spending full time on venereal disease control although 1 had recently been transferred to routine public health duty in her county. Two of these full-time nurses were located in large cities. Of the remaining 15, 7 were routine public health nurses having charge of one or more districts in a county; these were also assisting in the clinics in contact investigation and follow-up of patients under treatment. Six of the nurses stated that they were acting as supervisors for large districts in the state nursing program. One nurse had married and another died a few months after completing the course of instruction. In all, 20 were actively engaged in some phase of the venereal disease control program.

Average Number of Patients Treated Per Week	20,000

* One Health Officer who had been called into the Army failed to answer this part of questionnaire.

INFORMATION OBTAINED BY FIELD VISITS

The field visits were made by two members of the teaching staff. This was done to obtain firsthand information relative to the value of the 4 weeks' course, with special reference to clinic management and application of epidemiological methods in the different clinics. An effort was also made to see how the private physicians were functioning in coöperation with local health units in the syphilis control program. Sixteen physicians and 5 nurses were visited in 3 states, Missouri, Arkansas, and Mississippi.

The physicians taking courses in syphilis control have returned usually to small communities, though a number entered upon full-time venereal disease control work in larger centers of population. The latter usually devoted 3 or more months to training in our clinic.

One of the most valuable achievements noted was the better coöperation of the private physicians with official health agencies as a result of their broader concept of the syphilis problem. Many of the county health officers pointed out that practitioners who had formerly been disinterested or who had actually opposed the work had acquired a changed viewpoint and were giving wholehearted support to the syphilis control program. This change in attitude was also observed by the public health nurses who were interviewed. As an example, may be mentioned the private physician who, out of his own funds, had constructed a building to house a syphilis clinic in his community. Another private practitioner organized a campaign to obtain an appropriation from the city council of a small country town for a community health center. He was successful in his effort and was very proud of this accomplishment. It was learned from the health officer that this physician had not been particularly interested

in public health before taking the postgraduate course.

Observations made in the clinics conducted by health officers confirmed the information obtained from the questionnaires with regard to the use of more modern diagnostic and epidemiological procedures.

Upon the public health nurse falls most of the burden of contact investigation. These field visits indicated that the nurse who had completed the course was able to carry on this work more efficiently and was also instrumental in stimulating the physicians to get names of contacts of acute cases. These public health nurses were also training other nurses in the local health units in the principles of syphilis control.

SUMMARY AND CONCLUSIONS

The manner in which the short intensive course of instruction in syphilis control has influenced the postgraduate physicians and nurses has been reviewed. The course has been given to 115 physicians and 33 public health nurses from 11 states. The private physicians and the health officers have adopted more modern methods for diagnosis and treatment. Procedures such as darkfield and spinal fluid examinations are being used by physicians who, before taking the course, had not made use of these diagnostic aids.

The attitude of the private physicians toward the syphilis control program has been markedly improved and there has been better coöperation with health agencies in all phases of the syphilis control program.

The administration of syphilis control measures by the local health officers has improved as a result of better understanding of the syphilis problem. Contact investigation, which had been neglected, is now a routine public health procedure. Public health nurses who have taken the course have been particularly helpful in this phase of the

work and have trained other nurses in the local health departments.

In general, our 3½ years' experience in training personnel in syphilis control has led us to believe that much can be accomplished with the short intensive course of instruction.

U. S. Quinine Supply

THE Reconstruction Finance Corporation recently announced that 500,000 ounces of the 2 million ounces of quinine that it had purchased on the recommendation of the War Production Board had been lost at sea. The Netherlands Indies which has supplied the world with 90 per cent of its cinchona bark and derivatives now being cut off, it becomes a problem to know how the annual consumption of the United States of 3½ million ounces of quinine can be supplied. It was expected that the trade and private consumers had between one and two years' supply on the shelf.

The Federal Loan Administration announced that the Defense Supplies Corporation had purchased 1½ million ounces and had agreed to purchase cinchona bark equivalent to more than 3

million ounces, arranging for its immediate shipment to Australia for transshipment to the United States. This is expected to supplement the supplies obtainable from Peru, Bolivia, Brazil, Venezuela, Colombia, and Guatemala. The United States Government and private American drug interests have fostered experimental work recently in South America looking toward the production of types of cinchona yielding higher amounts of quinine.

Announcement was also made that substantial progress had been achieved in the manufacture of true synthetic quinine through the U. S. Public Health Service. Unlimited quantities of atabrine can be produced in the United States and it was expected that there was little likelihood of shortages in quinine itself for its essential purposes.

Human Equine Encephalomyelitis and St. Louis Encephalitis in California, 1939-1941*

BEATRICE F. HOWITT

*The George Williams Hooper Foundation, University of California
Medical Center, San Francisco, Calif.*

IN previous reports^{1, 2} it had been demonstrated by means of the serum neutralization tests and by recovery of the active agent itself, that the virus of western equine encephalomyelitis has been responsible for human cases of the disease in California for some time past. Antibodies against the St. Louis encephalitis have likewise been found among the population in similar geographical areas of the two central valleys of the state. Because the equine type of encephalitis has now become recognized as a clinical entity in man, the earlier study has been continued and a summary of the findings from 1939 through October, 1941, is herewith presented. Subsequent to the earlier articles, Davis,³ Cope and Maytum,⁴ and van Wageningen⁵ have published on the clinical aspects of the disease, and Buss and Howitt⁶ have presented a detailed study of human equine encephalomyelitis as seen in Kern County, Calif. Because the test for neutralizing antibodies has proved an aid in the differentiation of neurotropic virus diseases, the physicians are now better able to evaluate the etiology of their cases, separating those with mild encephalitis from those having non-

paralytic poliomyelitis, where formerly many were reported as the latter disease.

NEUTRALIZATION TESTS

The serum neutralization test as used in this study was employed essentially in the same manner as previously described,² except that rabbit serum was added to the broth diluent rather than distilled water. Two dilutions of each virus were made from a 10 per cent mouse brain suspension in Ringer's solution. The weaker dilution was about 10 times, and the stronger 50 times the least amount of virus that killed 50 per cent of the mice upon titration. The serum and virus dilutions were added in equal parts, left overnight in the refrigerator, and inoculated intracerebrally into young white mice. A serum was considered positive if it neutralized both dilutions of virus, and weakly positive if it only protected against the higher dilution. Because of the many tests performed with the same technic over a long period of time, and because they were repeated on the weakly positive sera, no differentiation has been made in computing the final results. All tests showing some degree of protection have been included as positive in the tables.

Protection tests were run routinely against the St. Louis virus of encephalitis.

* Aided by a grant from The National Foundation for Infantile Paralysis Incorporated.

litis (originally obtained through the courtesy of Dr. W. T. Webster of the Rockefeller Institute) and the virus of western equine encephalomyelitis, Br. strain of human origin.¹

Table 1 gives the comparative results of the test for the years 1939, 1940, and 1941. Sera were received not only from the two central valleys of the state but a large number from the Bay Region and adjacent coastal towns. They were all from individuals having disturbances of the central nervous system, including poliomyelitis. The sera containing antibodies for the encephalitic viruses were from residents of either the Sacramento or the San Joaquin Valley, only one being positive for the St. Louis strain in the Bay Region. However, in 1941, two sera from the coastal counties of Santa Cruz and San Mateo, south of San Francisco, were found to neutralize the St. Louis virus. Both were from adults showing neurotropic disturbances and

were without contact with the inland valleys. Another serum positive for this virus was also obtained from Sonoma County north of the Bay Region. The only other protective sera have been from 6 children referred to San Francisco hospitals from the valley districts. They were all positive to the western equine strain.

The percentage of positive tests for the equine virus has fluctuated each year for the different regions as shown in Chart 1. There was an increase for Kern County during 1939 and 1940, dropping in 1941, while in Fresno County there has been a steady increase for each year. It may be of significance that more sera were positive only to the St. Louis strain from Tulare County than from the other endemic areas. The other valley counties reported many cases of encephalitis for 1940 but very few for 1941. In fact, the total number for these regions fell markedly during

† Sera neutralized the virus

0 Sera did not neutralize the virus

‡ Weakly positive

CHART 1—Comparative Incidence of Western Equine and St. Louis Encephalitis in the Central Valleys of California for 1939, 1940, and 1941 as Determined by the Serum Neutralization Tests

this year. While the figures given in the table are based on the number of sera received or on autopsy material, yet undoubtedly they do not represent all of the cases, because the blood was taken mainly from patients coming to the county hospitals, and many were probably missed.

During 1939, the number of tests that were negative to the encephalitic viruses increased for Fresno County with a corresponding decrease in those positive to the equine or the St. Louis strains. Because many cases were diagnosed as poliomyelitis and the latter virus was isolated three times from

fatal cases in Fresno in 1939, it seems probable that the negative sera were mainly from poliomyelitic patients. Kern County likewise reported as many as 73 (63.7 per cent) cases of poliomyelitis during the same year.⁶ In 1940, encephalitis again increased in the same areas while poliomyelitis declined.

In 1941, all types of neurotropic virus diseases had decreased. The reduction was especially noticeable for the more northerly counties in the Sacramento Valley. Only 11 sera were received, by contrast with 33 in 1940. Twenty-one (63.6 per cent) of the latter had been positive for the western equine virus, while only 5 (15.1 per cent) reacted with the St. Louis strain. Three were positive for both viruses. The decrease in encephalitis for 1941 may be interpreted as due to a change in climatic conditions, because the rains were heavy and unusually prolonged during the early months of the year and thus unfavorable for the early appearance of an insect vector.

In Table 2 are given the complete data of the neutralization tests on sera from the two central valleys for 1939, 1940, and 1941, supplemented by the records for 1937 and 1938. The total numbers represent all the cases diagnosed as some form of neurotropic virus disease, including those of poliomyelitis. Except for 1940 the percentages have remained about the same for the sera positive against the western equine virus.

RECOVERY OF THE VIRUS AND
MORTALITY RATES

While the differentiation of neurotropic virus diseases in California has been based largely on the results of the neutralization tests, yet findings on human autopsy material have also been available. Recovery of the viruses of both poliomyelitis and of western equine encephalomyelitis has given evidence of their presence in these localities. Previous reports have described the isolation of the latter strain from 2 human cases in 1939² and later from 2 others in 1940.⁶ Another human strain has been recovered in 1941 from a 9 year old boy in the Fresno General Hospital.

During 1939 the virus of poliomyelitis was obtained from 3 out of 5 fatal cases diagnosed as bulbar poliomyelitis in Fresno County and again from one in 1940. It was also isolated from the feces of 6 individuals in Kern County in 1941. It is evident therefore that this virus is endemic in these areas and that the neurotropic diseases, poliomyelitis, western equine and St. Louis encephalitis, may at times be confused, particularly the abortive or non-paralytic forms or even certain types of paralysis.

In 1937 when epidemic encephalitis first became a problem in California, there were 40 deaths out of 102 cases reported to the State Department of Public Health or a mortality of 39.1 per cent.⁷ Twenty-eight of these patients were in Fresno County with 13 deaths or 42.8 per cent fatality. In 1940 the deaths had fallen considerably in the lower part of the central valleys according to the report of Dr. H. L. Wynns of the State Department of Health.⁸ The rate was 18.6 per cent of 43 cases in Fresno County and 15.2 per cent of 46 cases in Kern County. On the other hand, the fatalities in the more northerly districts varied from 20 to 25 per cent.

In 1941 the death rate was lower in the valleys. Two (4 per cent) out

of 50 neurotropic cases died in Kern County and 3 out of 35 (8.5 per cent) in Fresno County. The latter included one case of poliomyelitis. Unfortunately not all of the fatalities had confirmatory laboratory findings, so that while they were reported as encephalitis, the actual type frequently remained undetermined. However, one may not always recover a virus from post-mortem material, especially if it is sent from a distance. The western equine strain was isolated but 4 times from a total of 34 brains received since 1937. Four of the latter proved to be poliomyelitis, 3 were due to the tubercle organism, one to *Torula histolytica*, one to rabies, and one to *Staphylococcus aureus*. Two of the remaining cases were diagnosed as bulbar poliomyelitis but the others were probably due to encephalitis most likely of the equine type.

AGE AND SEX DISTRIBUTION

Tables 3 and 4 show the age and sex distribution of the cases having antibodies against the equine and the St. Louis viruses for the years, 1939, 1940, and 1941. It is significant that more males than females are affected. This holds true for each year and for both types of viruses. Over twice as many males as females, or 176:82, showed antibodies for the 2 encephalitic strains.

When the data for the 3 years are combined and the ages are subdivided as in Table 4, the male cases still predominate for both viruses. The differences in sex are less noticeable among the younger children through the 12th year, when apparently the chances of exposure to an insect vector are more evenly distributed. On the other hand, owing to the more exposed outdoor life of the men in these agricultural regions, males over 13 years of age seemed to run a greater risk of becoming infected than females. This is also true for the

TABLE 3

Age and Sex Incidence for Encephalitic Cases in Valley Areas

Year	Positive to Virus	Total Number	Sex		Total Number Cases Tested	Age Incidence According to Positive Neutralization Tests			
			Male	Female		Under 1 Year	1-9 Years	10-19 Years	20 Years and Over
1939	W. equine	83	51 (61.4%)	18 (21.6%)	82	8 (9.7%)	23 (28.0%)	20 (24.3%)	17 (20.7%)

	W. equine and St. Louis		16 (19.2%)	2 (2.4%)		1 (1.2%)	5 (6.0%)	4 (4.8%)	4 (4.8%)
1940	W. equine	105	61 (58.0%)	29 (27.6%)	102	19 (18.6%)	24 (23.5%)	14 (13.7%)	30 (29.4%)
	St. Louis alone		9 (8.5%)	6 (5.7%)			2 (1.9%)	6 (5.8%)	7 (6.8%)
	W. equine and St. Louis		15 (14.2%)	8 (7.6%)		3 (2.9%)	5 (4.9%)	7 (6.8%)	8 (7.8%)
1941	W. equine	70	28 (40%)	19 (27.1%)	69	7 (10.1%)	10 (11.5%)	12 (17.3%)	14 (20.2%)
	St. Louis alone		20 (28.5%)	5 (7.1%)			7 (10.2%)	9 (13.0%)	10 (11.5%)
	W. equine and St. Louis		14 (20.0%)	9 (12.8%)		1 (1.4%)	2 (2.9%)	9 (13.0%)	6 (8.7%)

similar age periods in regard to exposure to the St. Louis virus.

All ages are affected by the western equine virus, varying from 16 days to 74 years, with the largest proportion in the group 0-10 years. There are also many cases among males 10 to 30 years old. In Kern County alone, for 1938, 1939, and 1940⁶ the largest number of equine encephalomyelitic cases were under 10 years of age with many among infants under 1 year.

In California the ages most affected by St. Louis virus seem to lie between 13 and 30, with few cases among the

younger groups, the range in age extending from under 1 to 66 years. One 6 months old baby had antibodies only for the St. Louis strain. A month old child, 5 infants of 2 months, and another infant of 3 months were positive for both the St. Louis and the equine viruses. The serum of a 20 day old baby with encephalitis showed weak neutralizing ability when first tested for the St. Louis strain but was negative 2 weeks later. The mother had strong antibodies against this virus and it seems probable that the child had acquired them through placental trans-

MAP 1—Geographical Distribution of Western Equine and St. Louis Encephalitis in California for 1939, 1940, and 1941 as Determined by the Serum Neutralization Tests

fer. Antibodies for the equine virus predominated in the child's serum but were absent in that of the mother.

The individuals showing a combined antibody response were mainly from 7 to 30 years of age. More of these were positive among the younger groups than were those reacting to the St. Louis strain alone.

tends to concentrate in the center of the wide valleys over extensive areas. This portion is also the center of population and of agricultural industries. The distribution of the disease for the years 1939, 1940, and 1941 may be followed by reference to Map 1. It must be taken into consideration, however, if the large cities are designated, that the patients resided mainly in the outlying districts. The majority have originated from rural areas, small farms or homes of about an acre on which chickens and other domestic fowl, cows or other animals may be present. Though the affected place may be free of such animals, they are often found somewhere in the neighborhood. Everywhere in the endemic areas, mosquitoes are present some time during the spring or summer.

It is of interest that the individuals showing antibodies to the St. Louis virus often reside in the same regions

where the equine disease is prevalent both among man and horses. A glance at the map shows that the similarity of distribution is striking.

SEASONAL INCIDENCE

Each year there is a definite seasonal occurrence for both of the encephalitic diseases. The first human cases may appear about May or June in the southern counties of the San Joaquin Valley and later in those further north. They are prevalent during the hot summer months and often continue into the fall or even winter if the weather remains warm. This condition is especially noticed in Kern and Fresno Counties.

SEASONAL DISTRIBUTION OF WESTERN EQUINE AND ST. LOUIS ENCEPHALITIS IN CALIFORNIA

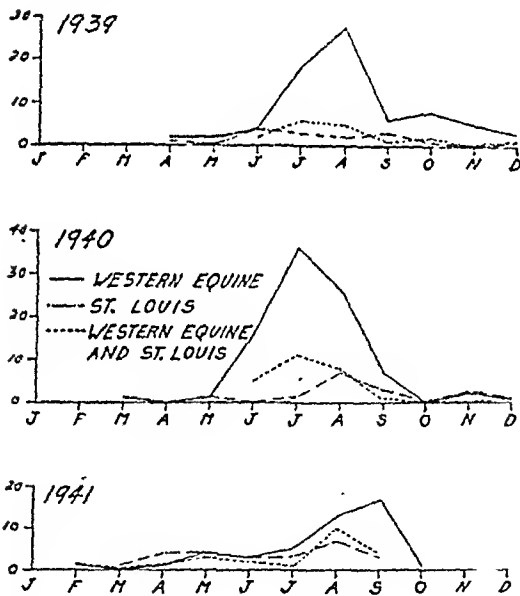

CHART 2—Seasonal Incidence of Western Equine and St. Louis Encephalitis in the Central Valleys of California for 1939, 1940, and 1941

The highest incidence of the equine type throughout the two central valleys, as estimated by the number of serum neutralization tests was in August for 1939, in July for 1940, and in September for 1941 (see data in Chart 2). The cases with antibodies only

for the St. Louis virus exhibited the same seasonal appearance with a slightly higher incidence in August. When antibodies were demonstrated for both types of viruses, the cases usually followed the distribution given for the equine form.

In order to correlate the seasonal appearance of encephalomyelitis in the human population with that among the horses, the official reports to the State Department of Agriculture have been used through the courtesy of Dr. C. U. Duckworth. It was noticed that if the data for the valley counties as a whole were compared, the frequency of the equine disease paralleled that of the human, but if they were considered by separate counties, the greatest incidence for the horses occurred approximately one month prior to that for man. This regional difference is in all probability conditioned by the late appearance of an insect vector in the more northerly sections of the state.

It should be emphasized that the cases in horses which come to the attention of the veterinarians, have been diagnosed almost entirely by the clinical symptoms unconfirmed by laboratory findings, while the majority of human encephalitides have been differentiated by the serum neutralization test. Nevertheless, in the counties with the highest incidence, sick horses and human cases of encephalitis are often in close, but not necessarily intimate association. Affected individuals may not possess a horse, yet sick animals might be within one-half to one mile distance.

Not only is the seasonal incidence coincidental for the two encephalitic diseases but poliomyelitis also occurs simultaneously in the same areas. In Kern, Tulare, and Fresno Counties the incidence of poliomyelitis may fluctuate each year but nevertheless sporadic cases are always to be found. Both these diseases are definitely endemic.

PRESENCE OF NEUTRALIZING ANTIBODIES IN HORSE AND FOWL SERA

The simultaneous presence of neutralizing substances for both the St. Louis and the western equine viruses in many human sera and the demonstration of antibodies against the latter strain in the sera of domestic fowl⁹ prompted the further examination of blood samples of animals from different regions. Since a preliminary report has already been made,¹⁰ only a brief statement is deemed necessary. It was found that antibodies against the St. Louis and the western equine viruses could be demonstrated in a certain percentage of both horse sera and those of domestic fowl; chickens, turkeys, ducks, pigeons, pheasants, and peacocks, and that more positive results were obtained from endemic than from non-endemic areas. The sera of 32 chicks hatched in the laboratory were all negative. Comparatively few sera showed antibodies only for the St. Louis virus. However, the percentage was high, 77.7 per cent of 46 animals, when the sera yielded reactions for both types.

With the exception of a few horses, most of the animals tested were apparently normal. It has been demonstrated by Ten Broeck¹¹ and by Howitt⁹ that domestic fowl may remain clinically unaffected by the equine virus and yet carry the latter in the peripheral circulation for a certain period of time. Further experiments have shown that young chicks may remain well after inoculation with the St. Louis strain and yet harbor virus in the blood through the 30th hour. The possibility of these inapparent infections in relatively insusceptible animals, especially fowl, strongly suggests the barnyard as a potential reservoir for the encephalitic viruses, particularly since both types have recently been recovered from the mosquito, *Culex tarsalis*, by Hammon,

Reeves, Brookman, Izumi, and Gjulin.¹² Hammon and associates have also¹³ reported the results of testing the sera of a large group of birds and mammals in the Yakima Valley and found a higher percentage neutralizing the equine or the St. Louis viruses among domestic than wild animals.

NEUTRALIZATION TESTS ON SERA OF NON-ENCEPHALITIC INDIVIDUALS

It has always been a question as to what interpretation to place on the results of the neutralization tests for the encephalitic cases. Does a positive test indicate contact with the disease and how many members of the population might be expected to have neutralizing antibodies? Buss and Howitt⁶ have reported the tests against the western equine virus made on sera of normal individuals in the endemic areas of Kern County. Of 82 friends and relatives of acute cases, the sera of only 6 (7.3 per cent) were positive, while 97 (86.6 per cent) of 112 sera from acute encephalitic patients in the same areas reacted to the equine virus. Of 82 bloods from cases of poliomyelitis, only 5 (6.0 per cent) neutralized this strain. Thus a normal expectancy of 6.6 per cent positive neutralization tests for the equine virus is probably correct for a comparable group of non-encephalitic individuals in an endemic region. When one takes into account the findings on sera tested from a non-endemic district like the San Francisco Bay region together with the low figures for the normal group in an endemic area, the higher percentages for the acute cases acquire definite significance and the test would appear of value as a diagnostic aid for the equine disease.

The results, however, are not as conclusive in regard to the value of the neutralizing antibodies against the St. Louis virus, since many human beings in the general population may be

affected in an endemic region. In a series of 144 sera received from people in the Bay Area during the past 3 years, only one (0.6 per cent) has given a weakly positive reaction. In another group of sera from poliomyelitic cases in the coastal city of Tacoma, Wash., only 4 (6.4 per cent) were positive to the St. Louis virus as compared to 28 per cent or 7 times the number reported by Hammon¹⁴ and by Hammon and Howitt¹⁵ for a group among non-encephalitic people in the endemic Yakima Valley, Wash.

Blood from a comparable group of either poliomyelitic patients or normal contacts has been tested from the valley regions of California. Of 95 sera, 15 (15.7 per cent) were positive for the St. Louis virus or an expectancy of over twice as many for this disease among the normal population in the same areas as for the equine strain. The percentage of positive tests in this endemic region was about one-half that among the normal individuals as for those in the Yakima Valley, where a higher incidence is found for the St. Louis virus.^{14,15} From the data collected it would seem that the presence of antibodies for the St. Louis strain may not be as etiologically significant in the diagnosis as their presence for the western equine virus in a similar area.

Notwithstanding, it appears that the St. Louis virus is the responsible agent for a number of the acute encephalitic cases in certain districts and that the presence of protective substances in the blood would be of diagnostic importance among the younger age groups. Positive tests for this strain alone were obtained on the sera of 2 encephalitic infants under 1 year and on those of 7 when in combination with antibodies for the equine virus. Six children under 6 years of age were also positive only to the St. Louis virus. The ages responsible for most of the positive

tests, however, remain in the older groups, mainly 12 to 30 years.

In most localities the western equine virus is apparently the more predominant agent of the 2 diseases as shown by the greater number of positive protection tests among the acute cases, although the St. Louis type has been more in evidence in Tulare County during 1940 and 1941. A total of 140 tests were positive for only the equine strain as compared to 55 for only the St. Louis during the past 3 years, or over 2½ times as many for the equine virus. Although the St. Louis strain itself has not so far been recovered in California, yet it seems likely that it is present, but not of as great a significance as the western equine virus.

NEUTRALIZATION TESTS ON SERA FROM OTHER CALIFORNIA DISTRICTS

While the major portion of the blood samples have come from the two central valleys of California, yet a small number have also been received from the southern part of the state. No positive tests were obtained against the equine virus until 1941 when the serum of one man from Orange County contained neutralizing antibodies. The patient resided in the town and seldom went elsewhere. Horses, however, have been known to contract encephalitis in the same county, so that the virus is probably to be found.

It seems probable that the St. Louis virus may likewise be responsible for human cases in these districts, since in 1938 encephalitis was reported in Riverside. At that time 6 (46.1 per cent) of 13 sera were positive for the St. Louis virus and none for the equine. The serum of one was weakly positive at first and became stronger after recovery. Seven sera did not react to either strain, although 3 of them were tested again several months after the onset. It seems likely that the St. Louis virus was responsible for this

small outbreak even though no active agent was recovered.

Because the eastern virus of equine encephalomyelitis has recently been reported in horses as far west as Texas,¹⁶ there might be a possibility of such an occurrence along the Pacific slope. Sera have been received from many encephalitic patients in the coastal counties but all have been negative to the western virus. Likewise certain individuals in the central valleys have been clinically typical of encephalitis but without antibodies to the viruses used even after repeated tests. For this reason 11 sera from Kern County and an equal number from the Bay region and neighboring counties were tested against the eastern equine virus. Ten cases positive to the western strain from the valleys were also included. All sera so far have been negative except from one patient in Alameda County. He had been given large amounts of drugs and antimeningococcus serum as well, so that there is a possibility of an inhibitory action on the virus. Unfortunately no more serum was obtained to determine whether the blood became negative later.

DISCUSSION

From the clinical histories and from the results of many neutralization tests made each year, it seems evident that the virus of western equine encephalomyelitis has become endemic for man in California, probably for a longer period of time than can be estimated. Undoubtedly many cases have passed as non-paralytic poliomyelitis. Although the disease has never reached the epidemic proportions reported by Leake¹⁷ in 1941 for North Dakota and the northern midwestern states, yet the constant recurrence each year in the same localities renders a burden on the community and leads to a condition of disquiet in the rural population during the summer season. It is true that

many cases recover without residual effects, but on the other hand all stages of the disease may be seen, hence the physicians are becoming cognizant that permanent defects to the nervous system may be expected. The neutralization test has been of value in the diagnosis of these cases that now are referred to the urban physician from rural communities for consultation. Often they appear many months after the acute attack, with eye defects, personality changes or a state of mental retardation bordering on imbecility. These residuals have been less frequent among adults, although eye troubles and headaches may persist for some time.

The history of a particular case illustrates the sequel. A 5 year old boy was taken ill in 1937. He had convulsions, was weak, emaciated, and was expected to die at any time, but recovered. His blood gave a positive neutralization test for western equine virus and was checked again in 1938. The boy improved physically but lacked coordination and spoke incoherently. In 1941, 4 years after the onset of the disease, he had grown strong but was mentally defective and still lacking in coordination.

Since it is now known¹² that the mosquito, *Culex tarsalis*, is capable of carrying the western equine and also the St. Louis virus, every precaution should be taken against mosquito bites in endemic areas; children especially should be protected. The attack rate of infants and young children under 12 years has been high in the valley regions, contrary to the findings of Leake¹⁷ in North Dakota, where the adults were mainly affected.

In 1937, when cases of encephalitis first became of importance in the state, the evidence seemed to indicate the virus of St. Louis encephalitis as the active agent. Over 50 per cent of the encephalitic patients had neutralizing

antibodies for this strain in their blood but no virus was found.¹⁸ After recovery of the western equine strain from man in 1938 and when the serum neutralization tests indicated the widespread incidence in these regions, the latter disease took precedence and the significance of the St. Louis encephalitis was correspondingly minimized. A combination of circumstances at the time of first reporting suggested that the antibodies for the St. Louis virus, especially if together with those for the equine, had been acquired previously. Many of the sera were from people in the older age group who could have had an earlier infection. Many individuals were migratory laborers and it was suggested that they had brought in the disease to the state or had acquired it through contact with their neighbors.

From experimental evidence and data collected since that period, it seems that the previous impression of introduction by the migrants, largely prompted by testing only human sera, should now be corrected. The finding of antibodies for the St. Louis virus in sera of horses, domestic fowl, and wild mammals, together with their presence in the blood of infants under 1 year, furnishes convincing evidence that this virus has been endemic in the state for some time, although it has not as yet been recovered from human or animal tissues. While there was no very marked difference in percentage between the number of tests positive for the St. Louis virus from normal people (15.7 per cent) and those with encephalitis (27.7 per cent), yet undoubtedly clinical cases are present.

It is probable that one is dealing with two types of encephalitis in the same community, due to two different viruses. Experimentally the strains are immunologically and serologically distinct, but by producing a mixed infection in monkeys it has been shown¹⁹

that a highly virulent western equine virus may take precedence, inducing the symptoms and the lethal effect. The equine strain is recovered post-mortem even though the St. Louis virus may be found in the blood during the first 48 hours after inoculation. Antibodies may be only weakly positive for the latter while those for the equine are promptly evident. It is possible therefore to have neutralizing substances in the blood due to a simultaneous infection with the two separate viruses. That this dual infection may explain the presence of both the equine and the St. Louis antibodies in the same human serum, has been proposed recently in regard to the outbreak of encephalitis in the Yakima Valley.^{14,15} The possibility of the dual infection has been given further credence after recovery of both types of viruses from the mosquito as previously mentioned.

Mosquitoes have long been in association with both human and equine cases of encephalitis in California and since the disease is prevalent during the periods of greatest mosquito infestation and in irrigated, cultivated areas conducive to their propagation, it seems probable the same vectors are likewise the responsible agents for the encephalitides in this state.

SUMMARY

The study of encephalitis in California, based largely on the serum neutralization tests, may be summarized for the 3 years 1939, 1940, and 1941:

Of 498 human sera from cases of neurotropic virus disease in the central valleys including poliomyelitis, 213 (42.3 per cent) neutralized the virus of western equine encephalomyelitis, 55 (11.5 per cent) of 475 sera only the St. Louis strain, and 62 (13 per cent) both viruses. If the total amounts for the 3 years are considered, it is shown that 140 tests are positive only to the

western equine virus, exclusive of those in combination with the St. Louis strain, as compared to 55 for the latter virus alone or over $2\frac{1}{2}$ times as many for the equine.

One hundred and forty-four sera from the San Francisco Bay region were negative to the western equine strain with only one (2 per cent) weakly positive to the St. Louis type, although 3 sera from other coastal counties reacted to the latter strain alone.

The western equine virus was recovered from 3 human brains and that of poliomyelitis from 3 others during the 3 year period.

There were over twice as many males as females among the total number of encephalitic cases, although when the ages were subdivided, no sex distinction was noticeable in the youngest age groups infected with the equine virus. All ages were affected by both types but the majority of cases were under 10 years for the equine, and in the years 13 to 30 for the St. Louis strain.

Cases of both the western equine and the St. Louis encephalitis were found mainly in the rural agricultural, irrigated sections throughout the two large Central Californian valleys with a definite seasonal occurrence for both diseases that rises to a peak in July or August or even into September.

A normal expectancy of 6.6 per cent positive neutralization tests for the western equine virus was found among the normal population in an endemic area as compared to 15.7 per cent for the St. Louis strain in the same environment. Consequently more reliance may be placed in the test as a diagnostic aid for the equine disease than for the other.

The sera of 32 encephalitic cases were negative to the eastern equine virus of encephalomyelitis.

Of a small group of sera tested from Southern California during the 3 years only one showed antibodies against the

western equine strain, although this virus has been isolated from horses in similar localities. Six cases of encephalitis from one county, however, had neutralizing antibodies against the St. Louis virus.

Occasional residual effects to the central nervous system may be expected after infection with the virus of western equine encephalomyelitis, especially among the children.

From the epidemiological, clinical, and laboratory evidence one may conclude that the virus of western equine encephalomyelitis has become endemic in the central valleys of California for man and animals and that the St. Louis strain is likewise closely associated. From the finding of antibodies in the sera of fowl and mammals in endemic areas and in children under 1 year of age, it is apparent that the St. Louis virus has been in California for some time and is not imported from the mid-western states as formerly proposed.

ACKNOWLEDGMENTS—Appreciation is extended to the various county health departments of the state for their kind coöperation in obtaining and sending sera and autopsy material from the different cases. Particular thanks are due to Dr. W. C. Buss, Dr. N. Twissellmann, and Dr. Joe Smith of Kern County Health Department, to Dr. H. M. Ginsburg and the Staff of the Fresno General Hospital, and to the County Health Officers, Dr. H. Shaughnessy of Sutter-Yuba and Dr. Lee Stone of Madera. Appreciation is likewise extended to Dr. K. F. Meyer, Director of the Hooper Foundation, for his helpful criticism and to William van Herick for assistance with the charts and map.

Tuberculosis Case Finding in Institutional Populations*

The Use of 35 mm. Fluorograms Among the Mentally Ill

HERMAN E. HILLEBOE, M.D., RANDALL B. HAAS, M.D.,

Passed Assistant Surgeon, U. S. Public Health Service, on duty as Chief of Medical Unit, Division of Social Welfare, St. Paul, Minn.; Passed Assistant Surgeon, U. S. Public Health Service, Miami, Fla.; Passed Assistant Surgeon, National Institute of Health, U. S. Public Health Service, Bethesda, Md.; and Superintendent, Anoka State Hospital, Anoka, Minn.

IT has long been common knowledge that any institutional population is particularly subject to endemic diseases such as tuberculosis. Not only is there a high prevalence of the disease in populations of many institutions, but there are also characteristic and inherent difficulties in its control and treatment in any such situation, especially when the commitment of its inmates to the institution was not a result of the disease. The problems that arise may be considered as primarily epidemiological but complicated by financial and other practical considerations over which institution heads and staffs generally have only limited control.

In any but a tuberculosis institution, an administrator's concern about the disease assumes a peculiarly baffling and progressively serious nature as new advanced cases appear among the inmates. If, however, a hospital or other institutional superintendent had at his disposal a method by the use of which, at mod-

erate or small expense, he might identify early sources of tuberculous infection whose presence in his institution is most dangerous to it, a great part of his tuberculosis problem would be solved. It is with the use of such a technic that the present paper is concerned. Granting the importance of other aspects of tuberculosis control as they apply to a congregate population, the present discussion will be confined to the practical matter of early and accurate detection of cases of pulmonary tuberculosis in one type of institution, a state hospital for the mentally ill.

Among institutional populations, the mentally ill are numerically of considerable importance; in the United States nearly 500,000 such patients are hospitalized in state institutions alone. Of that number a significant proportion were tuberculous before commitment or have become so in the course of residence. Since the type of institutional medical care available in hospitals for mental patients does not effectively control the disease, the need for special tuberculosis case finding is felt perhaps more keenly in this sort of population

* Read before the Epidemiology Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

than in any other. Especially is the statement true whenever hospitals for the mentally ill are handicapped by shortage of personnel or funds, and lack of facilities for chest examination, particularly by roentgenogram.

OBJECTIVE OF THE PRESENT STUDY

It was with some of the foregoing considerations in mind that the Division of Public Health Methods of the National Institute of Health and the Medical Unit of the (Minnesota) Division of Social Welfare began, in 1939, a co-operative experiment to test the efficiency of the 35 mm. fluorogram. The work previously reported by de Abreu¹ from South America and Holm² from Denmark had already served to strengthen the feeling that the 35 mm. fluorogram might well be the answer to the question of inexpensive mass case finding. There has now been tested in the Anoka (Minnesota) State Hospital a practical portable fluorographic apparatus which seems admirably suited for use as a screening device in large institutional populations, particularly in states with a number of institutions. The objective of the study was to determine the usefulness and accuracy of 35 mm. fluorograms in the roentgenographic detection of pulmonary tuberculosis.

The plan of testing was to take small (35 mm.) films and, for definitive diagnostic purposes, simultaneous large (14" x 17") x-ray films, of all patients who could coöperate, and of all employees. As the plan eventually worked out, about 400 of the 1,264 large films were taken some time before their corresponding small ones; but the remainder were taken simultaneously.

It was recognized at the outset that because of the nature of their illness it is difficult to obtain uniformly good x-ray films of mentally ill patients. Due to physical deformity, many patients could not be placed in proper position;

many also resisted the efforts of employees to assist them. It was in some instances, therefore, necessary to give the patients strong sedatives before attempting x-ray examination of them. It was necessary, almost routinely, to bind the upper part of the patient's body to the cassette, so as to obtain and maintain reasonably good positioning. In many cases the patients could not coöperate by taking a deep breath and holding it during the exposure. In evaluating results of a comparison of small and large x-ray films one must therefore remember the handicaps under which both were taken.

Apparatus—The apparatus for the experimental study is of simple construction and consists essentially of an H-shaped cast iron standard, a rotating-anode x-ray tube, and a light-tight metal box. The latter, in the shape of a truncated pyramid, has attached to one end a Patterson fluorescent screen (type B) and to the other a Zeiss Contax camera with an f, 1.5 lens. The camera is focused on the exact center of the fluorescent screen. The distance from the screen to the target of the rotating anode tube is 42". The machine is not expensive nor is it difficult to transport, and can be used with any transformer that will deliver a 150 milliamperere current at 60 to 90 kilovolts. Such a transformer, usually found in state institutions, can easily be connected to the machine and can also be calibrated without great difficulty.

Reading the films—Prior to, and entirely independent of the reading of the 14" x 17" plates, 35 mm. films were read by transmitted light with direct magnification viewers (Leitz) by two physicians (H.E.H. and R.B.H.), neither of whom is a roentgenologist. It should be made clear that the object of the reading of the small films was not definitely to diagnose pulmonary tuberculosis, but rather to find parenchymal lesions of the lungs in all pa-

tients needing further study for final diagnosis. Accordingly, the 35 mm. films were classified as follows:

1. *Abnormal*, with immediately apparent clearly visible, definite shadows of the lungs that appear characteristic of reinfection type tuberculosis
2. *Suspicious*, with markings of any kind in the parenchyma of the lungs that could not immediately be interpreted as definitely abnormal but were also not within the range of normality of appearance
3. *Negative*, with no abnormal or suspicious markings in the parenchyma of the lungs, or with only the types of shadows ordinarily interpreted as representing calcification from first infection tuberculosis, or old thickened pleura

Later the 14" x 17" films were interpreted by a qualified roentgenologist with extensive experience in reading chest roentgenograms. The National Tuberculosis Association's recommendations were followed in classifying lesions as *minimal*, *moderately advanced*, or *far advanced*—with two additional categories, "reserved diagnosis or suspect" and "no reinfection type tuberculosis."

The sample—In the Anoka (Minnesota) State Hospital in the first 8 months of 1940, it was possible to obtain a 14" x 17" x-ray film and a 35 mm. film of reasonably good quality for each of 1,264 cases. The institution population was distributed by age and sex as shown in Table 1.

RESULTS OF THE SURVEY

As of January 1, 1940, it was known that 66 of the 1,264 patients in the hospital had reinfection tuberculosis. There were 39 minimal, 17 moderately advanced, and 10 far advanced cases, according to the N.T.A. classification. In addition to the 66 known cases of tuberculosis the 14" x 17" x-ray film survey found 180 new cases; 119 of which were minimal, 57 moderately advanced, and 4 far advanced. Of the total of 246 cases, representing 19.5 per cent of the population, 158 were minimal, 74 moderately advanced, and 14 far advanced. In addition, there were 56, or 4.4 per cent of the population, classed as "reserved diagnosis" cases.

As is shown in Table 2, the 35 mm. films were read as abnormal or suspicious in 301 cases, 23.8 per cent of the group examined. There were thought to be definite abnormal shadows in 182 cases (14.4 per cent) and suspicious lung markings in 119 (9.4 per cent). However, 11 of the 35 mm. films read as abnormal and 20 as suspicious were "over-read" since the corresponding 14" x 17" plates were interpreted as negative for tuberculosis. The "over-reading" applied, therefore, to 31, or only 3.2 per cent of the 962 negative cases. Errors of interpretation were due mainly to the difficulty, on small films, of visualizing the apices and the extreme

TABLE 1

Age	Total	Male		Female	
		Number	Per cent	Number	Per cent
Total, all ages	1,264	387	100.0	877	100.0
15-24	9	3	0.8	6	0.7
25-44	266	82	21.2	184	21.0
45-64	649	197	50.9	452	51.5
65 and over	340	105	27.1	235	26.8

It will be noted that more than two-thirds of the group were women and that the age distribution was quite similar for each sex.

periphery of the upper lung fields. However, aside from the 31 cases, examination of the 35 mm. films of 1,264 patients interpreted 13.3 per cent as

having definite abnormal lung shadows, and 7.3 per cent, suspicious lung markings.

Considering in each instance the reading of the 14" x 17" films as a standard, the 35 mm. films missed 11.4 per cent, or 18 of the 158 minimal, and 4.1 per cent, or 3 of the 74 moderately advanced

Case 2,406—Nodular tuberculosis in the left apex and fibrosis in the first interspace, also right apex, first and second interspaces.

(Apices are hard to visualize on 35 mm. x-ray pictures of uncoöperative mental patients because of the difficulty of obtaining deep inspiration and good positioning during exposure. Likewise, fine fibrosis is difficult to visualize on small films with present technic.)

TABLE 2

Comparison of X-ray Findings on 14" x 17" and 35 mm. Chest Films by NTA Diagnosis on 1,264 Mental Patients at Anoka (Minn.) State Hospital, 1940

Reading of 35 mm. Film	Total Cases	Diagnosis by 14" x 17" Film (NTA Classification)				
		Minimal	Moderately Advanced	Far Advanced	Reserved or No Reinfection Suspect	Type Lesion *
		Numbers				
Total	1,264	158	74	14	56	962
Abnormal or suspicious	301	140	71	14	45	31

Suspicious	119	61	11	..	27	20
Negative*	963	18	3	..	11	931
		Percentage Distribution (NTA)				
Total	100.0	100.0	100.0	100.0	100.0	100.0
Abnormal or suspicious	23.8	88.6	95.9	100.0	80.3	3.2
Abnormal	14.4	50.0	81.0	100.0	32.1	1.1
Suspicious	9.4	38.6	14.9	48.2	2.1
Negative*	76.2	11.4	4.1	19.7	96.8
		Percentage Distribution (35 mm. Readings)				
Total	100.0	12.5	5.9	1.1	4.4	76.1
Abnormal or suspicious	100.0	46.5	23.6	4.7	15.0	10.2
Abnormal	100.0	43.3	33.0	7.7	10.0	6.0
Suspicious	100.0	51.3	9.2	...	22.7	16.8
Negative*	100.0	1.9	0.5	...	1.1	96.7

* Includes first infection type lesions and thickened pleurae.

lesions; but none of the 14 far advanced cases. In other words, the small film technic missed only 3 of the 88 advanced cases of greatest potential danger to the population group involved. Eleven of the 56 "reserved diagnosis" cases were read as negative on the small films.

The 3 moderately advanced cases (all found to be clinically inactive) which were missed in the reading of small films were also of types apparently difficult to interpret except on 14" x 17" plates of better than average quality. In order more fully to explain this statement, the large film x-ray findings for each of the 3 cases are given below:

Case 865—Old fibrosis both upper lobes, thickened pleura both upper lobes.

(Old fibrosis does not show up well on 35 mm. films if the linear or fibrotic markings are very thin, and especially if the case shows both fibrosis and thickened pleura.)

Case 1,305—Right lung was clear. There is extreme thickening of the pleura on the entire left side. Evidence of old tuberculosis in left apex and left clavicular region.

(The 35 mm. film showed an area of increased density over the entire left side, suspected as pleural thickening, but no markings were noted in the parenchyma.)

However, it may be said that review of the small films for cases 865 and 1,305, and direct comparison with cor-

responding large films, has indicated that these two types of lesions would rarely be missed in future readings of small films. Once seen, they are thereafter quite recognizable.

DISCUSSION

Tuberculosis creates serious administrative and epidemiological problems within institutions with large populations unless cases are diagnosed before they reach a communicable stage. Early and accurate detection of advanced cases is a matter not only of epidemiological, but also of economic importance both to institution heads and the general public alike. Primarily for the protection of the inmates and employees of the institution itself, it therefore becomes an obligation of the responsible officials of the institution to identify and segregate its communicable cases of tuberculosis. Furthermore, since many types of institutions (those for the mentally ill, among others) parole their inmates, there is further obligation to the general public not to release into it known sources of infection. All these advantages of early diagnosis are, of course, in addition to the more personal ones for the diseased individuals themselves.

In the type of institution in which this study was made, early diagnosis is especially advantageous in that, in states having a number of hospitals for the mentally ill, one may be set aside and used for the tuberculous. In that way specialized clinical and surgical services need not be provided in all institutions, nor need there be so many (usually part-time) trained consultants as would otherwise be necessary. Administratively, such a plan should work out quite well in that it is less expensive, more practical, and more effective as a means of communicable disease control than it is to have a large isolation unit in each institution.

In view of experimental results re-

ported here there appears to be an excellent place in the field of institutional tuberculosis control for the small x-ray film method. Although in the experiment the physicians who read the small films "under-read" 21 of the 246 films showing pulmonary tuberculosis, all but 3 were only minimal lesions and those were clinically inactive. If the testing apparatus had been used in actual practice as a screening device preparatory to further diagnostic testing with 14" x 17" x-ray films and, appropriate clinical and laboratory procedures, its efficiency, in so far as the finding of dangerous cases is concerned, would indeed have been very high. On the other hand, the error of "over-reading" as abnormal or suspicious those films with no evidence of disease was also relatively not large—31 of 962 cases. Again, in actual practice, 31 large plates would have been taken unnecessarily—a not very serious loss considering the number of cases found and the size of the population examined.

However, there is every reason to believe that when technicians and the physicians who interpret films acquire further experience, both kinds of errors will be materially reduced. After they have handled a number of cases of a specific type, it seems reasonable to assume that the quality of films on that type can be improved, although there will always be some patients that are difficult or impossible to examine by x-ray successfully. When physicians gain more experience in what to look for in the small films and understand more fully the significance of what they see, interpretation will undoubtedly become more accurate.

The low cost of the 35 mm. fluorogram is obviously one of its strongest recommendations, if it is to be used in mass case finding in very large populations. Aside from the cost of equipment, electricity and the salary of the staff, each 35 mm. x-ray film costs

about 1 cent processed—or about 1/50 as much as a 14" x 17" plate. In addition, less personnel, time, and storage space are required for 35 mm. films than for larger films. A technician, an assistant technician, and a clerk, acting as a crew, can produce, depending on the coöperation of patients and employees of the institution, from 200 to 500 small films a day with ambulant subjects. In institutions whose inmates can coöperate (prisons, for example) the number per day can be doubled. Hence a unit, such as has been described, if used on a state-wide basis with a traveling crew, would ordinarily need to spend only a few weeks at any but the larger institutions. In most states at least one x-ray film a year could be taken of all suspected persons or even all not known to have tuberculosis, and adequate follow-up, an essential of tuberculosis control, could be maintained.

It should not be inferred from what has been said that the 35 mm. fluorogram is considered the only alternative to the 14" x 17" x-ray film. The paper film technic has been fully developed and such plates are much less expensive than standard 14" x 17" films. However, there is a tendency among many physicians not to accept paper films with the same degree of reliance as they do standard plates. Potter, Douglas, and Birkelo³ have been very successful with a 4" x 5" film but the apparatus is quite expensive and the operating costs are greater (films, developing, storage, labor). Fluoroscopy is also satisfactory from a diagnostic point of view, but, again, it does not produce a permanent record of the kind considered adequate to guide subsequent clinical management; and, more important, there are few flouoroscopists in state institutions. Because of the restrictions involved in the use of any of the three methods just mentioned, it is believed that the 35 mm. fluoro-

gram offers the most practicable solution to the problem.

SUMMARY

A portable and inexpensive fluorographic unit, using 35 mm. film in a standard camera and transportable 200 milliamperage x-ray equipment, was tested in a state hospital for the mentally ill. Of the more than 1,200 patients, all of whom were tested, few could coöperate and many were deformed and otherwise physically not good subjects; yet the apparatus was efficient in discovering a very large proportion of the advanced cases of tuberculosis in the population. In fact, over 150 cases of tuberculosis, in addition to the 66 known before the experiment, were identified in the course of it. The readings of small films were checked against independent interpretations of corresponding standard x-ray plates, with the result that the errors of both over- and under-reading were found. In neither respect was the lack of correspondence great enough to cause concern about the essential accuracy of the technic as a screening device, even among uncoöperative subjects.

The results of the experiment lead to the belief that the technic and apparatus used are, even without further refinement,* sufficiently accurate to warrant their widespread adoption by states for use among institutional populations, particularly if the state has a number of large institutions. Routine "screening" or identification of communicable cases of tuberculosis, and periodic rechecking of suspicious cases, would then be possible at a small fraction of the cost of using standard 14" x 17" x-ray film equipment. If also segregation and

* As a result of this preliminary work, the Division of Public Health Methods of the National Institute of Health has set up a comparative photoroentgenographic study under Dr. Willis Beasley, psychophysicologist, to make an intensive technical evaluation of these procedures. Dr. Beasley assisted in the development and construction of the experimental fluorograph used in this study.

treatment were further centralized, the advantages to the patients themselves, the institutional employees, and the general public would be very important not only from the point of view of communicable disease control but also from that of substantial economy.

Industrial Nutrition and the National Emergency^{*}

HENRY BORSOOK, PH.D., M.D.

California Institute of Technology, Pasadena, Calif.

IN the present national emergency, we are sparing neither men nor money to provide the best engines of war that we can contrive. In mechanized warfare, from 6 to 18 men must work at home for every man stationed in the first line of defense. The whole fabric of our industrial organization, which is the backbone of our national emergency, depends on the productive effort of the men and women in industry. Our modern knowledge of nutrition can make a major contribution to this effort whose benefits will remain long after the present crisis has passed.

There is an interesting example in a recent experiment which suggests how improved nutrition may, in an unexpected manner, alleviate the strain of work in industry. Rats are sensitive to high pitched sounds. Many rats, after a few days, are thrown into convulsions by exposing them to a high pitched note for one minute a day. These convulsive seizures occur whenever the note is sounded. It was found in young animals 2 to 4 months old already on a fairly good diet that the susceptibility to these seizures can be reduced by liberal supplements of the vitamin B complex. Although some improvement was obtained with thiamin alone, the best results were obtained by supplementing the diet of each rat with 20 gammas daily each of thiamin, riboflavin

and pyridoxin. This supplement with synthetic vitamins was as effective as 2 gm. of brewers' yeast daily.

It will be interesting to ascertain whether workers exposed to a great deal of noise require more than ordinary amounts of the vitamin B complex.¹

It has been observed in Britain that the improvement of the diet of workmen which was not up to standard for good health was followed by increased output without any increased effort and also by a reduction in the number of accidents; as a result, many factories are now providing a good meal for their employees.

Nutrition workers have known for some time that men maintained on vitamin deficient diets become more easily fatigued and suffer from lassitude and loss of interest in work. The more active the person the sooner the severe symptoms develop. Other symptoms known to occur in vitamin deficient individuals are depressed mental states, soreness of muscles, and backache. The significance of these symptoms for men engaged in war work needs no emphasis.

These considerations would not concern us if it were known that our workmen consumed adequate diets; unfortunately the opposite is true. A number of studies indicate that millions of people in this country are living on diets below the safety line. It has been said "nutritional diseases in all probability constitute our greatest medical problem, not from the point of view of deaths,

^{*} Read before the Western Branch, American Public Health Association at the 12th Annual Meeting in San Diego, Calif., May 25, 1941.

but from the point of view of disability and economic loss."

In a well known survey carried out by Stiebeling and Phipard of the U. S. Department of Agriculture, it was found in four great geographical regions from coast to coast among employed non-relief workers that the distribution of good, fair, and poor diets was approximately as follows: poor 50 per cent, fair 35 per cent, and only 15 per cent were classed as good. The chief difference between "good," "fair," and "poor" diets is in the amounts of vitamins and minerals they contain.

The extent of malnutrition in this country is worse than these figures indicate because the diets classified as "fair" are in reality unsafe diets. The following were the standards for a "fair" diet:

Protein	50	gm.
Calcium	450	mg.
Phosphorus	88	mg.
Iron	10	mg.
Vitamin A	3,000	I.U.
Vitamin B ₁	333	I.U.
Ascorbic acid	30	mg.
Riboflavin	0.9	mg.

The amount of vitamin A is not sufficient for normal dark adaptation in many individuals. The amount of vitamin B₁ is barely sufficient to prevent beriberi, with no margin of safety. There is barely enough protein to prevent loss of body protein. The amount of vitamin B₂ is insufficient protection against cheilosis. It is an astonishing and disquieting fact that in a country as rich as the United States in food, transportation, and industrial organization, only 15 per cent of the employed workers had diets better than this.

A nutrition survey was carried out in Pasadena between May and August, 1938, under the direction of W. L. Halverson, Medical Health Officer of Pasadena, and the writer. Our findings in this region confirmed those of Steibeling and Phipard.

In any planned attack on malnutrition in the war industries we must consider the causes of the widespread malnutrition in this country. One of them is no doubt economic—29 per cent of the non-relief families during the years 1935 and 1936 in villages and cities had incomes below \$1,000 a year. It would have been impossible even with expert nutritional knowledge for these people to purchase a "good" diet. Investigation showed that only 25 per cent of these families bought "fair" diets, 75 were "poor." The economic factor would be the most important one if our objective were limited to the prevention of severe nutritional diseases such as xerophthalmia, beriberi, pellagra, and scurvy.

When optimum health is our objective, then the economic factor becomes of secondary importance. Referring again to the survey of Steibeling and Phipard, 43 per cent of the non-relief families living in villages and cities had incomes between \$1,000 and \$2,000 a year. In this group, where the economic factor is unimportant as a determinant of the quantity and quality of food provided, only 25 per cent had "good" diets, 65 per cent were "fair," which we have seen is really an unsafe diet, and 5 per cent were bad. In the group of families with incomes of \$5,000 or more, 65 per cent had "good" diets, 30 per cent were "fair," and 5 per cent were bad.

Anyone who has computed the amounts of the nutritive essentials in actual dietaries knows that even the well-to-do, who can eat what they want, as much as they want, and are reasonably intelligent about it, do not and cannot, unless they possess the necessary technical knowledge, obtain a diet which will afford optimum health. The chief difficulty is in obtaining enough of the vitamin B complex. What then is the situation among those whose incomes are in the middle and lower brackets?

How much could we save in dispensaries and hospitals if the middle and lower classes, who comprise by far the great majority of our population, had first class diets from childhood?

One reason for this widespread inadequacy in our diet is well known. Modern processes remove the vitamins and minerals from wheat, corn, and sugar in the milling and refining. Today less than 10 per cent of the vitamin B complex in the wheat grown in this country is actually eaten by human beings, although subclinical vitamin B deficiency is widespread in all economic classes.

There is no use in crying over spilled milk. The nation will not eat whole wheat flour and bread. Furthermore it would require profound changes in the milling industry. In attempting to solve industrial nutritional problems, we must, at least for the period of the emergency, use such methods as do not call for a revolution in processing methods, nor for great changes in eating habits. Or we shall fail. The new knowledge of nutrition with the aid of the new food technology can provide an optimum diet for all, if we will be rational about it.

Whatever measures are taken, there is one absolute prerequisite; that is that public health and other officers concerned with protecting our food have at least some appreciation of the new knowledge of nutrition. I heard not long ago of one of our state officers concerned with food and drug inspection who stated that he did not need vitamins, that very few people do. When informed of a recent federal rule that vitamins be classed as foods, he stated that he would do all he could to obstruct such a rule from becoming permanent.

I wish this outspoken officer would submit to the simple experiment of living on a diet which contained no vitamins for as short a period as 2

months on the familiar washed casein, cane sugar, lard and, possibly by way of indulgence, cow lick for minerals. He could be allowed water ad lib. If he survived the 2 months' experiment, I am sure he would become a zealous evangelist for vitamins. New converts are the most devout.

The education of the public to the harmful consequences of polluted drinking water and milk has greatly helped the public health officer in providing safe water and milk. In the same way, if the public knew that among the consequences of mild but prolonged nutritional deficiency disease in adults are, among others, the many aches and pains of middle and old age, defective vision in dim light, dyspepsia, thinning of the bones, it would be easier for public authorities to provide a richer vitamin and mineral intake in our staple foods, it would encourage food processors to provide the public with a variety of foods adequately enriched with vitamins and minerals.

Conversely, an informed public will appreciate the limits of what can be expected from improved nutrition. Many diseases and illnesses, for example, cancer, measles, diphtheria, pneumonia, cannot be significantly alleviated or cured by any conceivable increase in vitamin and mineral intake. It is well to be on guard against the uninformed enthusiast (public, private, or commercial); he is nothing less than a quack.

Turning now to the special problem of improving the nutrition of our workers in the war industries, whatever methods are chosen, they must satisfy these requirements:

1. There must be no disturbance in factory routine.
2. There must be no interference with production.
3. We must not, by trying to get men to eat unpleasant foods, give them cause for complaint.

There are many difficulties to be overcome in this field. The first is that the level of popular nutritional education is so low. This is responsible in part for the high percentage of so-called "fair" diets in the middle classes. Another difficulty is that people are slow to change their eating habits. Most people in this country refuse to eat whole wheat bread. It is more serious than a joke that many men simply detest green vegetables and will not eat them. Many will not drink milk. The common superstitions regarding acid and alkaline foods, many so-called allergies, and the necessity for keeping on the "alkaline side" deter many from eating citrus fruits. I am sure every reader can multiply such examples.

Another serious difficulty in the problem of industrial nutrition is the poverty of cooking and serving facilities in our factories and in the homes of these workers. This is especially true in the new industries which have sprung up so rapidly. For example, one important factory in this region contains cafeteria facilities for 3,000 men; there are 26,000 men employed in that plant. Another employs 50,000 men and has no cafeteria facilities. The most that it can supply is hot coffee. If one passes by such a plant at noon, he sees men sitting on the pavement or in their cars eating sandwiches made of white bread, drinking bottles of soft drinks. The neighboring "hot dog" and hamburger stands serve a thin meat or cheese sandwich, again on white bread. Only here and there does one see a bottle of milk. Fruit is even less in evidence, and vegetables are, of course, out of the question apart from the occasional innocuous pale looking lettuce leaves in a sandwich.

How do these workers eat at home? Here is a typical case. Four unmarried young men live together. One of them cooks for the four in return for which he does not pay any rent. The food consists essentially of some fried

meat which is quickly prepared. They fill up on potatoes, white bread, some butter, practically no fruit or vegetables, although they are living in Southern California, and cream for coffee, but no milk.

There is no prospect at present of obtaining space or facilities for either preparing or serving even one meal a day in these new plants. This is not intended as a criticism of the management of our war industries. They are concerned with the great problem of turning out airplanes, ships, and instruments of war as quickly as possible, and we must sympathize with them. Every available bit of space is used for production machinery. If we are going to be helpful, we must recognize their difficulties, accept their estimates of what they consider necessary in the way of plant machinery and plant routine, and adapt our recommendations to their difficulties as they envisage them. In any case, management knows the familiar and tangible problems of production. No one can criticize them for being unfamiliar with the less tangible factors such as the importance of good nutrition, especially when the effects are not immediately seen in production totals.

It is the task and duty of the nutritionist to try to improve the nutrition of the workers, and of the executives, without making demands which will curtail production, even temporarily. If we can do this, we have a case when we ask management and labor to be patient and wait for the long range beneficial effects of an improved nutrition to manifest themselves.

What lines of attack are open? The first line of attack which suggests itself is education in nutrition. Whatever methods are found suitable, I am certain that an intensive educational campaign will be necessary to insure the effective coöperation of both men and management. But it must be obvious

that if we wish to effect a significant improvement quickly, we cannot rely on education alone. As an example of the limits which can be achieved by educational methods alone, I may cite the case of milk—in the last 20 years, the per capita consumption of milk in this country has increased by only 4 per cent, in spite of a persistent and intensive educational campaign by public authorities from the federal government to teachers in schools. In addition, dairy products have now become expensive. I have already referred to the undesirability of attempting to disturb eating habits too much.

The special task of the scientific nutritionist is to ascertain what the nutritional problem is and, having ascertained what needs doing, to find practical remedial methods which management can accept. Our task does not end here. Whatever measures are adopted, to insure their effective and continued operation, a continued educational campaign must be planned and carried out in the plant and in the homes of the workers. The reasons are sufficiently obvious to need no elaboration here. We shall probably need and have to call on many social agencies. This, it seems to me, is the proper place of education in our national nutrition program—to assist positive measures, rather than to rely mainly on general education to improve the nutrition of the people. We have not time for that.

In this connection, I may quote from a recent article by Dr. W. H. Sebrell * of the U. S. Public Health Service:

Just a few years ago, I took the point of view that the way to correct these conditions was to try to stimulate the increased consumption of foods naturally high in these vitamins. I still think that this point of view is correct theoretically. Although I recognize that such a program, if it succeeds at all, will progress so slowly that it cannot

meet the extensive deficiency conditions in our population today; therefore, as I see it, the next best thing is to add these vitamins and minerals to foods which are consumed in large quantities, especially by the low income groups.

The new food technology can be very helpful here. The development of synthetic vitamins and vitamin concentrates is one of the important technological advances of our time. Seven vitamins can now be obtained more cheaply as synthetics than from foods or other so-called natural sources. In a recent release, the National Research Council emphasized that synthetic vitamins are identical in every respect—chemically, nutritionally, and medically—with those in foods. The same is true of vitamin concentrates. Good preparations containing synthetics or concentrated vitamins can be valuable supplements to even a good diet, and even more to diets which are restricted for whatever reason. The points to be considered in the use of such preparations are as follows:

1. What purpose are they intended to serve?
2. Would the use of any given concentrate really eliminate the deficiency it is aimed at?
3. Are they a good buy?

Regarding the general principle involved in the use of concentrates and synthetics, it is necessary only to quote from a release from the National Research Council:

... There is ample reason to believe that any population receiving a diet fully adequate in vitamins, minerals, and other nutritive essentials is better able to withstand the stresses and strains of war or threats of war. Unquestionably, millions of Americans are not eating diets adequate in all essentials.

One significant point in this release is the absence of any mention of food as such: meat, milk, eggs, vegetables, and cereals. A food is adequate or inadequate to the degree to which it contains nutritive essentials. Nutritive essentials serve their nutritional purpose

* Read at the conference of bakers, millers, and others to coordinate the introduction of enriched flour and enriched bread, Chicago, March 5, 1941.

whether they are grown in the field, salvaged from agricultural wastes and made edible, or entirely synthesized in a factory. One need only point to the profound change in modern medical therapy since synthetic vitamins have become widely available.

A step in this direction has already been taken in the fortification on a national scale of white flour with vitamin B₁ and nicotinic acid. The addition of vitamin B₂ so far is optional. It is desirable that fortification with vitamin B₂ be made obligatory in "enriched flour" as soon as possible, because vitamin B₂ deficiency is very widespread all over the country, much more widespread than any one of us suspected a few years ago.

Federal authorities now agree that all fats, butter, margarine, and lard should be fortified with vitamins A and D. By so doing, we not only add greatly to the nutritional value of the fats used by the poor—margarine and lard—but even the nutritional value of butter can be improved. For example, winter butter can in this way be made as nutritious as the best summer butter.

A few employers of labor in this country are already convinced that the productive capacity of their workers can be improved by improving their nutrition. In most cases, they have, at their own expense, supplemented the diets of their workers with vitamin concentrates. There are a number of reports in the press on this subject. It does not appear, however, that these efforts have been supplemented by an orderly and systematic study of the nutritional state of their workers before and after the vitamin supplements were

used, nor have they attempted to ascertain precisely what has been achieved by the vitamin supplement.

It seems to me that it is of the highest importance for public health nutrition that where measures such as these are taken the results of these measures be carefully recorded and studied. In spite of all the experimental work which has been done, the influence of diet on human health, on working capacity, on the incidence of accidents, and on the psychological state needs to be demonstrated by carefully organized and well controlled studies. We must be on our guard against extravagant statements and promises of what will be achieved. There can be no doubt that improvement in the health of the workers as a result of improved nutrition will be beneficial; but the particular respects in which these benefits will manifest themselves in this country remain to be demonstrated.

There is danger, of course, that the industrialist will be impatient and see in the scientific approach to these problems only another impractical academic survey which will take up a lot of time (of which we have none to spare at present) and money, and will end with unpractical and inconclusive results. Management must be made to see that, as an efficiency engineer cannot give any sound or useful advice without first appraising the existing mechanical situation, so the nutritionist must be allowed time, facilities, and opportunities to make a similar appraisal of nutritional status and facilities before he can make any useful recommendations.

The Rôle of Public Health in the National Emergency*

FELIX J. UNDERWOOD, M.D., F.A.P.H.A.

Executive Officer, Mississippi State Board of Health, Jackson, Miss.

PUBLIC health undoubtedly faces one of the greatest challenges today since its evolution as a science. A horizon which seemed bright only a short time ago with opportunities for fulfilling long-sought public health aims and needs has been darkened. Today, we realize that these clouds are a threat to our many years of planning and accomplishment and that our very right to life, liberty and the pursuit of desirable objectives in coming years depends upon the strength of the defenses we build now.

No nation can profess strength whose people are physically unfit for efficient service. Consequently any intelligent war effort must give a large measure of consideration to the health status of its civilian and military populations. The present conflict is no ordinary war, but is primarily one between the total production and efficiency of the countries involved. In this light, public health assumes a rôle of importance second to none, not only in developing military strength but in producing the equipment for fighting, and in maintaining morale.

Total war presents tremendous problems which we can hope to solve only through intelligent coöperation, careful planning, and a willingness to sacrifice. There is a job for everyone and if our

total effort is to be successful there must be a unity of purpose and a clear understanding of individual responsibility in this supreme undertaking for national safety and security.

Public health workers are more than glad to do their share in meeting the responsibilities of these times, and the medical and dental professions have demonstrated a like spirit. However, it cannot be emphasized too strongly that necessary service on the home front is equally as important as service in the Army. Even though we recognize aggressive war as our No. 1 problem, it behooves us not to be forgetful that a major phase lies in holding the health gains already made. We are deeply concerned, and rightly so, regarding the steady depletion of our trained personnel, as one by one our health officers, nurses, technicians, and sanitarians, on whom there have been spent substantial sums of money for training and equipment, report for needed military duty. We have expected that we would have to make some sacrifices, but it seems necessary to insist that there be a more equal distribution of all medical facilities, or the consequences may be regrettable.

The whole problem of drafting and calling to active military duty personnel employed in public health departments was considered at a special conference of State and Territorial Health Officers in Washington a few months ago. It was recommended that, in plans for

* Presidential address delivered before the Southern Branch, American Public Health Association, at the 10th Annual Meeting in St. Louis, Mo., November 10, 1941.

the war effort, the work of the official public health agencies be recognized as an essential part of the national program.

In spite of the steps taken in developing the Procurement and Assignment Service, it remains to be seen just what can be done with the limited personnel available to cope with the public health problems which existed before the emergency and as well to take care of the multitude of new needs which the present crisis has forced upon us. The large concentration of troops in camps and cantonments and the tremendous influx of new population brought about through industrial expansion have created problems of great magnitude in communicable disease control, sanitation, housing, medical and hospital facilities, education, recreation, and in many other related conditions essential to social development and public health. The Community Facilities Bill passed by Congress is expected to meet some of the need by providing funds for hospitals, including quarantine or isolation hospitals, clinics, malaria control, schools, recreation buildings, and many miscellaneous items.

In the meantime, upon what should we concentrate from a public health standpoint to achieve the most good with what we have? We cannot hope to tackle all needs, so the logical procedure is to begin with the most urgent and work on down the list, achieving all we can. It is my opinion that the first and most important needs would embrace the following:

1. *Communicable disease control*—with especial reference to the venereal diseases.

2. *Sanitation*—The very elemental phases of health work need more emphasis, particularly ordinary sanitation, safe water and milk supplies, protection of the food supply, sanitary methods of excreta disposal, and drainage.

3. *Industrial hygiene*—With production of tools and equipment being a primary essential to defense, the health of the worker

assumes a place of first importance. It must not be neglected.

4. *Rehabilitation*—Based upon the large number of rejectees we have had, which we feel is a good cross-section of the total population, it goes without saying that some action must be begun immediately to boost the physical status of these rejectees where possible.

The lesson that public health gains from the startling discovery that so many are incapacitated for active military service is that mere absence of disease does not imply that one is enjoying maximum physical efficiency and well-being. Consequently, the future will likely see greater emphasis than ever before on promotion and conservation of health as well as prevention of disease. It is time to begin applying on a universal scale the excellent store of knowledge we have been accumulating for some years for practising personal preventive medicine and hygiene. That knowledge, properly recruited, will strengthen immeasurably the nation's defenses. It remains for public health to assume the leadership in putting it to work, instilling in people a greater sense of personal responsibility for health.

The health status of our civilian population as reflected in the large percentage being rejected by the Selective Service boards is of grave concern to public health officials, and we should like to get something done about it. Even though it is impossible to correct the whole situation, 20 to 50 per cent of those involved are considered susceptible of rehabilitation.¹ Last October President Roosevelt indicated to his press conference that a plan is being developed for rehabilitation of the draftees who are classified at the time of their first physical examination as being susceptible of rehabilitation at a reasonable cost in a comparatively short time. To those who were doubtful about the possibility that draftees would

volunteer for rehabilitation or that they could be forced to correct remedial defects, the President responded with some legal opinions as to how such rehabilitation might be compelled once the draftee came under the control of his Selective Service board. Such a program would be largely experimental at first until sufficient evidence has been accumulated to make the process wholly effective. There is a note of hope in the President's proposal which promises some solution to a very complex problem, and which no doubt will exert a helpful influence on the whole civilian population in building physical fitness. The hope remains in spite of the delays which have followed.

The question was advanced at a recent Conference of State and Territorial Health Officers² as to whether American public health, within its present framework of organization, is equal to the task of supporting and enhancing military and industrial mobilization and at the same time not seriously depleting the program which has taken years to build. It is apparent that there must be some solution for meeting both civilian and military needs, for if the health of either group lags, the other will ultimately suffer from it. Consider, for example, how much time the soldier spends in territory outside the camp. What will it profit him to have the best of protection in camp if the first time he steps into the surrounding civil communities he contracts some infection which he brings back to menace the rest of the troops? Military public health in the long run, therefore, depends upon the status of civilian public health, and no more important preparation for national defense exists than meeting the health needs of both groups.

We are resolved, therefore, to do the best we can with the personnel and resources available—this in spite of the increasing number of public health

problems and the decreasing number of trained workers to fulfil present needs. Dr. Thomas Parran² tells us, after making some firsthand observations in England, that—

If we are to learn anything from the British experience on the medical front, we must reorganize our approach to the problem of medicine's contribution to the defense effort. The medical needs of the civilian population should be considered in all recruitment plans, and should be balanced against the military needs. . . . Medical personnel for military, industrial, and civilian health and medical services should be recruited on a quota basis, having in mind the service which each individual physician can render best. . . . The successful local organization of medical defense effort in Great Britain was possible because for two decades or more Britain has had a nucleus of trained medical officers of health. Without this nucleus, effective local medical defenses could not have been organized. We should take steps promptly to double the number of doctors with training and experience in public health and medical administration. In addition, there should be a comparable increase in public health nurses, sanitary engineers, sanitary inspectors, laboratory technicians, and other technical public health personnel. New training centers will be needed for the training of key persons who in turn will train others who will work under supervision in local communities.

Amid the demands and frustrations of our present crisis, such ideals do not seem possible of early realization. However, I do not believe it is too early to begin looking toward that day when peace shall come upon the earth again, and to make our preparations accordingly. For without doubt, we shall face a world in which many values will be changed, both social and economic, and many new responsibilities will be presented which we must be ready to meet. Public health has met the challenges of past crises, and has through its experiences in them developed new and improved technics which proved beneficial to succeeding generations. Let us hope that when we have emerged from the

present conflict, our contribution to lifesaving methods will have offset in some measure the tragic toll of the battlefield. Since we live in a day of almost revolutionary achievement, I sincerely feel that public health will not be found lacking in the advances which

may be made, or in meeting the demands of the future.

Memorandum Regarding Minimum Educational Facilities Necessary for the Postgraduate Education of Those Seeking Careers in Public Health*

IN view of the confusion which exists regarding facilities necessary for the proper education of professional public health personnel it seems timely for the Committee on Professional Education to state its present opinion. For the benefit of appointing bodies, teaching institutions, and candidates for a professional career in public health, the committee here sets forth what it believes to be the minimum facilities necessary for the adequate training of professional workers. It is subject to change and elaboration as experience accumulates.

I

Since public health itself is a specialty, all professional service in public health requires special education over and above the training inherent in the profession from which the candidate comes. For example: a physician entering the field of public health, already fully trained in clinical medicine, must also acquire competence in public health administration, epidemiology, vital statistics, community organization, etc.

II

To their great credit many present and past public health leaders obtained their training largely by experience. We recognize their attainments and acknowledge our indebtedness for their pioneer accomplishments. Nevertheless, (a) with today's rapidly accumu-

lating knowledge, (b) with the increased legal, social, and economic responsibilities of the public health profession, and (c) with the development of many superior teaching institutions, we believe special professional training in public health is best obtained at a well equipped teaching institution. Such training should be at the graduate level, that is, after earning the professional degree.

III

Special professional training for a public health career should include:

1. Skilled, organized, well integrated instruction, including laboratory exercises, under a variety of teachers who are recognized leaders in their respective fields, including a central group of those who devote full time to the teaching of public health.
2. Supervised field observation and experience in one or more well organized official or voluntary health agencies.

IV

1. There is great advantage in obtaining this special training in a teaching institution having immediate access to and coöperative assistance from the faculties of schools of the medical and biological sciences, engineering, education, social and political science, economics and business administration. While not all professional public health personnel need full

* Adopted by the Committee on Professional Education of the American Public Health Association, April 17, 1942.

- competence in all these broad fields, some will need considerable familiarity with several of them.
2. It is essential that the institution essaying to train professional public health personnel at the graduate level have a good library for reference work and ample laboratory facilities where students may have adequate space and apparatus to develop skills in such fields as bacteriology, engineering, statistics, and the like.
 3. It is likewise essential that such an institution have access to well organized health departments and voluntary health agencies which are willing to assist the school by providing facilities for supervised field training and experience. The performance standards of these agencies should be satisfactory to the school and their procedures familiar enough to the school so

that its teaching methods may be correlated with the student's observation.

4. There is considerable advantage in having all necessary facilities for training all types of professional public health personnel in the same institution so that they may participate together in certain basic courses.

THE PUBLIC HEALTH ADMINISTRATOR AND THE WAR

AS the strategy and economy of war develops, all local, personal, and group interests must give way to the national needs. This is a hard lesson to learn. To many it is distressing even to entertain such a thought. Faced with the oncoming shadow of deprivation and sacrifice, one is inclined to expostulate and remonstrate, fearing perhaps that if he does not do this his rights will be more adversely affected than will be the case with those who cry to high Heaven. One is naturally appalled, too, to find threatened the things to which he has given his life. But this threat to things is not nearly so serious as is the threat to life and soul; and the latter threat is essentially the one which each man and woman in every walk of life today faces: an inexorable and universal threat that all must meet. One may meet it in good spirit, courageously, and generously, to the benefit of his country and the glory of his own soul; or he may acquiesce half-heartedly, grudgingly, and stubbornly, to the jeopardy of the nation and his own deserved and final self-damnation.

How does all this relate to public health? Well, for the past year and a half there has been much speculation as to how war would affect (1) the public health, (2) public health work, (3) public health workers, and (4) the recruitment of new personnel. Actually, from a broad national standpoint, the first consideration is the only one of real importance, for in comparison with the necessity of maintaining the public health, the *way* in which this is done, by *whom* it is done, and the personal fortunes and comforts of those at present engaged in public health work fade into insignificance. While this philosophy has by now been generally accepted by those responsible for the public health, some have not yet reached the articulate and action stage. That this is the case was evidenced in the proceedings of a recent conference on public health and the war. This was attended by many public health administrators. In the early stages of the discussion, perhaps for the greater part of it, those present seemed to be chiefly concerned with how in the face of military demands they might maintain their staffs intact or nearly so. Beyond a doubt many of them had sustained grievous losses in personnel, and their evidence of distress was received with due sympathy. But

the conference seemed to get nowhere. The members were restless. One sensed that, while they regarded as serious this draining off of trained workers and the inability to replace them with similarly trained personnel, they felt it to be only one part of a situation which badly needed to be discussed from a broader standpoint. And then, amazingly, the air was cleared by two or three speakers who took an entirely new tack. They called attention to the fact that there is a war on, that in pursuing this war, and in spite of the morale-designed emphasis on the importance of civilian defense, armed forces after all play a part of some importance; that for the man power of these armed forces there must inevitably be a bottom-of-the-barrel scraping of physically fit individuals under 45 years of age; and that in these circumstances it becomes the duty and privilege of public health administrators so to shape their organizations and so to bend their programs as to yield generously, and even completely to the armed forces those on health department staffs who are competent, and fit, to serve in a military capacity. These speakers went on further to point out that the responsibilities of public health administrators were not to keep their staffs intact, but to maintain the health of the public regardless of the shortage of already trained personnel they might have to face today or tomorrow.

It was heartening to witness the responses to these perfectly clear-cut, logical, and realistic suggestions. Many of those present seemed for the first time to realize that in this emergency public health work *could* and *must* be carried on by older men, by men not necessarily completely robust, by women; that, in contrast, active, rough-and-tumble military duty can be sustained only by the young and hardy. These administrators were realists enough, too, to appreciate that in numbers, the under 45 years of age and physically fit individuals are necessarily limited; and on the basis of their experience they were quick to see that, just as in a budget, disaster invariably follows when a number of executives are drawing on the same item, so only one authority may wisely draw upon or hold in reserve the physically fit professional group in public health. In most instances, the authority so to draw must rest with the Procurement and Assignment Service, which in this field is the agency officially designated to meet the needs of the Army and Navy Medical Corps, and of civilian populations.

Generally then, it may be said that public health administrators are adjusting to meet the new demands. As the situation becomes more sharply defined, two things stand out clearly. The first is that the military services must have prior claim on public health's tough and active workers, and the second, that the problem which administrators in this field face is not to preserve public health organizations and staffs as they were, but to maintain the public health in spite of inadequacy in personnel. And they will do this. Public health officers are not themselves so far spent that they are unable to stoop and rebuild, even though it must be done with untempered and sometimes worn tools.

AN ADOLESCENT GIANT STIRS

UNDER a release date of March 30, the United States Public Health Service announced that a three day conference on the conservation of man power in war industries would be held in Washington, April 9 to 11. This announcement went on to state that "Even in normal times, 400,000,000 man-days are lost annually in industry because of sickness and accidents. A large part

of this wastage can be prevented. Representatives of the medical profession, governmental industrial hygiene services, management, and labor will participate in the discussion of ways and means to reduce industrial disability."

The meeting in question was held last month, so it is no longer news. It is nevertheless significant, for such an approach to the problems and practice of industrial hygiene is a far cry from the old factory's dingy first aid dispensary. A comprehensive attack like this is quite different, too, from the situation which existed in industrial hygiene when the most stable of its personnel was the small town "railroad surgeon," not always chosen for his skill, whose principal duty was an occasional amputation and whose retaining fee was a railroad pass for self—and for family, if possible.

Today, not only are the problems in industrial hygiene far more extensive in their range and more complex in their make-up than formerly, but practice in this field demands quite a different type of individual. In fact, to meet the needs, there must be a staff of experts rather than one person. The medical man on such a staff is far more concerned with placement-employment and with prevention of disease and disability than with salvage after accident or disaster. He must be detailedly informed as to manufacturing processes and alert as to their potential dangers to the workers employed. This industrial physician, too, must be a good enough practical psychologist to know the limits in precautions which human beings are likely to observe under stress of monotony and fatigue, and the physical and mental demands of the various jobs. Not only must he be a good clinician, but a pre-clinician as well if he is to discover trouble in its incipency. And finally, he must be able to interpret both to management and to labor the dollar and cents value of the money and effort spent.

Medical measures, though extremely important in industrial hygiene, do not by any means occupy the entire field. Engineering work is vital in lighting, heating, ordinary ventilation, and in air conditioning and removal of dust and fumes; in the guarding of dangerous moving parts of machinery, in the provision of adequate washing and toilet facilities and their placement, even in the character of flooring and the kind and time of cleaning done. The chemist also plays an extremely important rôle in making safe the handling of toxic or irritating materials or in finding substitutes for them, and the physiologist is much concerned with questions related to fatigue, varying pressures, lights and temperatures, and tolerances of one sort or another. The interest and coöperation of employers is essential too, if industrial hygiene services are to be organized and maintained, and understanding, appreciation, and support, on the part of labor must be insured.

It is easy to see that in this field there has been a bursting of old bounds. New qualities and new quantities, and new problems and new practices have arisen. Industrial hygiene no longer limits itself to preemployment examinations and first aid. Instead, it relates to all those measures, procedures, and precautions which are designed to make reasonably safe the working conditions of those in industry and which contribute directly or indirectly to the maintenance of the workers' health and efficiency.

A Selective Digest of Diversified Health Interests

D. B. ARMSTRONG, M.D., AND JOHN LENTZ, M.S.

AN EDITORIALETTE:

ALWAYS AND NEVER

"The trouble with medical training is that it is too individualistic and ultra-conservative"—a criticism heard not infrequently, especially at this time, with the broad trend toward socialization of all types of services, now to be materially accelerated by the war. Presumably medical organization should and will be adapted so as to make possible a greater social use of medical services, though it is profoundly to be hoped that its basic anchorage in the traditions of private medical practice will not be completely sacrificed.

Always, if there are to be real doctors of medicine, the study of disease must be highly individualized. It is people as individuals who are sick with human pathology. They must be treated and cured individually, and, now that personal hygiene is superimposed upon public sanitation, their diseases must also largely be prevented individually.

The medical student of human diseases finds an infinite variety of manifestations, and few if any hard and fast rules. The signs and symptoms with which he must become familiar are not statistically as classifiable as are births and deaths. Those who deal with more tangible facts and figures seem to the doctor a little too facile in drawing conclusions from medical data. The average, well trained doctor of medicine sometimes feels that if he could be as sure of *any one thing* in medicine as

some of his non-clinical colleagues are regarding *everything in medicine*, he would be a most fortunate doctor indeed.

Then, too, the doctor finds ideas and opinions in his art changing a little too rapidly to validate the concept of fixed and incontrovertible facts in medicine. He remembers, for instance, the recent history of poliomyelitis. He remembers back in 1912 when flies were definitely identified with the transmission of this disease. He recollects that this idea was unconfirmed and rather completely repudiated, now to come back strongly into the poliomyelitis epidemiological picture. He remembers when poliomyelitis virus vaccines were enthusiastically applauded, and then discarded. He readily remembers the ups and downs of nasal chemical blocking—over-exploited by lay writers in the popular medical science field. He recollects when the respiratory tract was considered by nearly all scientists as the one channel of entry of the poliomyelitis virus. Despised and spurned were those few crying in the wilderness about the importance of the gastrointestinal tract, which now comes very much into the limelight. Finally, he hears of the traditional and universal therapeutic splints being discarded for a hitherto unheard of but widely acclaimed physiotherapy.

From this it would appear that a degree of skeptical pessimism in medicine is a rather healthy state, out of which the physician must from time to time be shaken, if he is to participate in and contribute to organized medical and preventive medical progress—a dislodgment usually accomplished by the more

Please address samples of printed matter, comments, or other editorial contributions to the editors at One Madison Avenue, New York, N. Y.

optimistic social promoter or health educator. Yet there seem to be in medicine few if any "eternal truths," and perhaps only succeeding facets of the evolving and growing body of knowledge. To some men in clinical medicine all this must frequently refresh their memories of their professor of medicine, who was accustomed to orient his class at the beginning of his lecture series by admonishing the embryo physicians that "there are two words that do *not* appear in the vocabulary of medicine—*always* and *never*."

(Editorial Note: Third and last call! Won't you help us continue this series of "editorialettes"? There must be many subjects in the field of health education upon which you would like to express an opinion. Let us have your thoughts on any of these subjects. You may praise, criticise, or philosophize—provided it is done in not more than a hundred words. While we cannot guarantee publication, serious consideration will be given to your contribution.)

DISSENTING OPINION

Since the government embarked on its ambitious program to induce Americans to eat their way to health, we have had an opportunity to examine much of the literature and other publicity material which certain federal agencies, health organizations, and commercial enterprises have issued for popular consumption. We find that, with few exceptions, these materials are not sufficiently convincing or appealing to arouse Mr. and Mrs. John Q. Public to the importance of good nutrition. We have tried our hand at it and are ready to admit that nutrition is a difficult subject to publicize. Just why our efforts to date have been singularly lacking in popular appeal is anybody's guess. Perhaps we have yet to find the proper popular approach which the advertising specialist calls "the selling angle."

We wonder how the average person

reacts to the nutrition literature that is handed out here, there and yonder. Surely much of this material is read and the advice in it followed. On the other hand, a great deal of it must be cast into the nearest wastebasket. And we hardly blame the recipients. At this point, many people are "fed up" with nutrition (if we may turn a phrase!). And why not? The nutrition messages stem from so many sources and so many products are "plugged" as having outstanding nutritive values that we suspect a large proportion of the public is beginning to look upon the educational program as akin to a great sales-promotion venture. To add to the confusion, we are told by one authority in the field of nutrition that much of the so-called educational material now in circulation actually contains misleading information.

It would be too bad if this campaign missed the mark. Public health workers have demonstrated that they can perform a task of this nature magnificently—as evidenced by the nation-wide syphilis campaign. But the nutrition program, like Stephen Leacock's horse, seems to be "running off in all directions." As one authority sums it up: "Everyone is a nutrition specialist these days."

Now is the time to vitalize this campaign through the distribution of more effective educational literature sponsored by or endorsed by recognized scientific agencies. There is no place in this program for the flood of handouts obviously designed to promote the sale of certain food products. Any original and appealing ideas that will help "put over" the nutrition message will be welcomed and duly broadcast in these columns.

If you do not agree with the observations made here—speak up. We welcome rebuttal.

FILM NOTES

"Tuberculosis is sand in the gears of democracy's victory machine." Upon

this theme the National Tuberculosis Association has fashioned a new motion picture that is entertaining, instructive, and keyed to the stirring enterprise of winning the war. The picture is entitled, appropriately enough, "Sand in the Gears." It is an unusually good film which moves from beginning to end with the brisk tempo of a newsreel. Its timely message, lively pace, interesting photography, narration, and music make this a picture that all types of audiences will welcome.

"Sand in the Gears" pictures America as a great industrial giant whose future depends upon "three musketeers—the soldier, the sailor, and the laborer." The film stresses the fact that tuberculosis can easily sabotage our war effort as the heightened tempo of wartime industry is especially conducive to the spread of this disease. The resources which are available to combat tuberculosis are described and the audience is left with the feeling that we are well armed to carry out the fight against this ancient enemy.

One could criticise the film on only two counts: (1) Relatively too much emphasis seems to be placed on public facilities for tuberculosis control, with little or no reference being made to the rôle of the private practitioner, and (2) no mention is made of the growing tendency to employ women in war industries—a fact that will certainly have a bearing on the tuberculosis problem.

"Sand in the Gears" may be obtained from state or local tuberculosis associations or from the National Tuberculosis Association, 1790 Broadway, New York, N. Y. Tell your local theater manager about this picture. It has sufficient audience appeal to warrant its use on any theater program.

— — —

A set of seven silent film strips has been issued by the Metropolitan Life Insurance Company to accompany the booklets which make up the company's Health Heroes Series, a group of seven

biographies of prominent physicians and scientists. The film strips of the Health Heroes Series have recently been thoroughly revised. New scripts were prepared for each, with the advice and coöperation of various public health and educational leaders. The film strips are illustrated with authentic pictorial material gathered from notable collections in medical libraries, archives, and from other sources. While the strips are produced primarily for schools, they are also suitable for adult audiences. The series includes the following titles:

Madame Curie and the Story of Radium—This interpretation of Madame Curie's life, her devotion to scientific research, and her achievements is particularly appropriate for use in cancer control programs.

Edward Jenner and the Story of Smallpox Vaccination—The life of the great physician who discovered smallpox vaccination is portrayed against a background of contemporary events and personalities.

Robert Koch and the Discovery of the Tubercle Bacillus—Koch is presented as the young naturalist who became the father of bacteriology and opened a new era in public health.

Florence Nightingale and the Founding of Professional Nursing—The dramatic story of the first great nurse and her influence upon the profession turns modern at the end with a series of pictures depicting the variety of nursing careers open to young women today.

Louis Pasteur and the Germ Theory of Infection—The glory of scientific achievement is felt throughout this brief but inspiring story of the great scientist's life.

Walter Reed and the Conquest of Yellow Fever—The history of Walter Reed and his gallant helpers who led the attack upon yellow fever is, as its opening title claims, a great detective story.

Edward Livingston Trudeau and the

Crusade Against Tuberculosis—In this film, Trudeau's life story merges with the story of public health's great triumph over tuberculosis.

The film strips come in 35 mm. size and may be used in a delineascope or other slide projector equipped with a special attachment designed for running film strips. They are given without charge, upon request, as a permanent addition to film libraries of health, nursing, and educational organizations. Write to the Welfare Division, Metropolitan Life Insurance Company, 1 Madison Ave., New York, N. Y., for prints.

RECENT HEALTH PUBLICATIONS

You will want to see . . .

The Nebraska Health Almanac for 1942. Almanacs and mail order catalogs have always held a peculiar fascination for the public. Little wonder then that the Nebraska State Department of Health saw fit to issue a health publication designed—as was occasionally done years ago—along the familiar lines of an almanac. It is our belief that this publication will be widely used by the citizens of Nebraska and that at the year's end, copies will be as well thumbed and dog-eared as once was the family almanac. The publication is well stocked with current public health information and in addition contains a great deal of historical material. (Incidentally, we were amused by one typographical error in the Almanac which reads: "Wednesday, April 8, 1869, Harvey Cushing, pioneer *train* surgeon was born.") The Almanac is delightfully old-fashioned in appearance and up-to-the-minute in educational content. Write to the Nebraska State Department of Health at Lincoln for copies.

Annual Reports and How to Improve Them. The Social Work Publicity Council, 130 East 22nd Street, New York, N. Y., in announcing this publication states: "Here's your inoculation

against annual report fever—here's your special treatment to prevent frayed nerves when annual reports are being prepared." We agree that this excellent guide, from the knowing pen of Mary Swain Routzahn, is "just what the doctor ordered" for all those who struggle with annual reports. This 20 page guide offers a wealth of information on how to make a report interpretative, readable, informal, and attractive. Of special interest is the fact that it tells how to produce inexpensive annual statements. Mrs. Routzahn discusses annual reports from widely differing fields of public service, in the hope that such "case histories" might be helpful to report-writers in improving their own work. This excellent publication may be secured from the Council for the slight consideration of 50 cents.

Why Does Tuberculosis Run in the Family? The National Tuberculosis Association is distributing a new publication with this title. It was written by H. E. Kleinschmidt, M.D., the Association's Director of Health Education. For a discussion of the factors of heredity and resistance, measured against environment and exposure, this statement by Dr. Kleinschmidt, designed for the interest of the intelligent lay reader, excels anything we have seen in this field in clarity, simplicity, and intelligibility. Sections in the pamphlet, dealing particularly with home infection hazards, are especially commendable. The publication is highly recommended for welfare workers, nurses, teachers, and others. Consult your state or local tuberculosis association for copies.

All Eyes! This is the title of the twenty-seventh annual report of the National Society for the Prevention of Blindness, Inc. Year in and year out this organization issues annual reports that are distinguished by their neatness, compactness, easy readability, and photographs that rivet one's attention. The 1941 report is prefaced by a thoughtful

and timely foreword in which the society's president, Mason H. Bigelow, stresses the importance of good eyesight to our present military and industrial effort. The body of the report is devoted to a resume of the year's work which reflects, as always, an admirable record of service. This is the type of report one wishes to file and keep, so well is it executed. Write to the Society at 1790 Broadway, New York, N. Y., for copies.

HEALTH—You Owe It to Yourself, a leaflet issued by the Council of Social Agencies of the District of Columbia, 1101 M Street, N.W., Washington. This publication is planned for distribution to rejected draftees. Its contents will be extremely helpful and encouraging to young men who feel that rejection renders them useless for any type of war work. Specific directions are given in the leaflet regarding those agencies in the community that are available for the treatment of diseases and the correction of defects. A publication of this nature could be used to great advantage in all communities. If interested, write to the agency mentioned above for a copy.

What Is Heart Disease? This folder, issued by the California Heart Association, 277 Pine Street, San Francisco, is decidedly "flashy" and modernistic. In fact, one might wish that a little less novel presentation had been used by the association to inform the public of its program. Yet the text of the folder is well written and attractively illustrated with stylized drawings. While we do not "go" for too much modernism in health literature, we grant that this particular publication will stand out from the general run of health pamphlets and will therefore be popular with the public. We like the slogan which this folder carries: "Heart disease over forty—It may be weight—not fate!" Copies may be had by writing the organization at the address given above.

Prostitution and the War, Public Affairs Pamphlet No. 65, by Philip S. Broughton. Here is a complete and thorough-going analysis of the rising problem of prostitution on both the home and fighting fronts. "We can't afford the germs of syphilis and gonorrhea any more than we can afford the less deadly human saboteur," says Mr. Broughton. In this 30-odd page pamphlet, the author makes it abundantly clear why no sane community can allow the modern prostitution racket to keep a foothold within its borders. The pamphlet contains some interesting descriptive material on social conditions that have grown up in industrial centers. It also outlines the work of public agencies that are concerned with the control of venereal diseases. A notable feature of this study is the author's sane viewpoint toward prostitution. He maintains that "prostitutes are people" who, if handled with skill and understanding, can be rehabilitated. Stamping out prostitution is a broad community enterprise and Mr. Broughton calls upon all the public, voluntary, and private community services to help do the job. This excellent study has substance without preachment and moralizing. *Prostitution and the War* may be obtained at 10 cents per copy by writing to the Public Affairs Committee, 30 Rockefeller Plaza, New York, N. Y.

"IT'S AS SIMPLE AS THAT—"

Breathes there a health educator who has not spent hours staring into empty space while trying to reduce to simple terms the pontifical utterances of the experts? We admire the scientists' capacity to observe and record, but one could wish that their observations and deductions were expressed more frequently in clear, simple language.

As a simplifier of ponderous phraseology, President Roosevelt is a master. He clearly demonstrated this ability recently when a government official

wrote a letter on the subject of blacking out federal buildings during air raids. The letter, bristling with polysyllabic profundities, stated:

"Such preparation shall be made as will completely obscure all buildings occupied by the Federal Government during an air raid for any period of time from visibility by reason of internal or external illumination. Such obscuration may be obtained either by blackout construction or by termination of the illumination."

Upon reading this, the Chief Executive ordered a re-write job. "Tell them," he said, "that in buildings where they have to keep the work going, to put something across the window. In buildings where they can afford to let work stop for awhile, turn out the lights."

Here is a lesson in simplification which is well worth the study of every health educator—and here also is one example of why our President is so well understood by the general public.

ARE YOU AN AUDIENCE ENEMY?

Although the A.P.H.A.'s Annual Convention is not scheduled until October, there are probably many prospective speakers who are already at work on papers and addresses to be delivered at the 1942 meeting. Naturally every person who is to appear on the program wants to put his or her best foot forward—so we pass on to you certain helpful excerpts from an article by Dr. Eugene F. DuBois entitled "Audience Enemies" and published in *Science*, issue of March 13, 1942.

Dr. DuBois lists six audience enemies whose minor and major defects are best calculated to torture a scientific assemblage. Heading the list of audience enemies is The Mumbler, who drops his voice to emphasize important points or else talks to the lantern screen instead of the audience. He is apparently more interested in excreting words than in con-

veying information. The Slide Crowder comes next. He packs his slides with typewritten data and shows too many slides, as if to demonstrate his industry. He also wields a pointer or employs a flashlight that projects an arrow that swoops and darts all over the screen and ceiling like a hornet. A good slide—carefully drawn in India ink and stripped of all nonessential words and figures—needs no pointer-wielder. Then there is The Time Ignorer, who talks beyond the limit specified in the program or justified by common courtesy. He is evidently over-impressed with the idea that his paper is much more important than the program committee had imagined. Occupying fourth place is The Sloppy Arranger, who jumbles his material in a way best calculated to confuse the audience. He may have in the back of his head the idea that he can lead up to a climax and hold the audience in breathless suspense until in the very last sentence he can prove that the venous blood of the wimpus contains only 3 milligrams of gadgetyl chloride instead of 4 milligrams. Would it not be kinder to the audience if he followed newspaper technic and gave in a headline, early in the talk, some idea as to what and wherefore? Audience enemy number five is The Lean Producer whose paper consists of trivia, errata, omissia, et cetera; mostly et cetera. Last on the list is The Grasping Discussor, who can spoil almost any meeting. If he has been invited to open the discussion he has probably prepared a nice little paper of his own with scant reference to the paper upon which he was supposed to comment.

It is suggested by Dr. DuBois that the chairman of a meeting can do a great deal to protect the audience against these enemies—and he proposes that the chairman be given a new title: "Sole Protector of the Audience."

Speakers themselves can do much to perfect their technic of delivery by

pondering this list of audience enemies long before they mount the platform.

MAGAZINE ARTICLES

Recent popular magazine articles on health or of medical import:

"What Medical Specialists Do." (A chart compiled by medical authorities.) *Good Housekeeping Magazine*, April, 1942.

"Do You Want to Be a Nurse?" Dorothy Dunbar Bromley. *Good Housekeeping Magazine*, March, 1942.

"Women Without Men." Maxine Davis. *Good Housekeeping Magazine*, March, 1942.

"Health for Young America." Thomas Parran, M.D. *Parent's Magazine*, March, 1942.

"Headaches Are a Luxury." Helen Furnas. *Coronet Magazine*, March, 1942.

"How to Dodge a Cold—or Lick One." Lois Mattox Miller. *Better Homes and Gardens*, March, 1942.

"A Dozen Don'ts That Save Lives." Charles B. Scully. *Better Homes and Gardens*, March, 1942.

"Do You Really Know What to Eat?" Paul de Kruif. *The Reader's Digest*, April, 1942.

"Germ Killers from the Earth: The Story of Gramicidin." John Pfeiffer. *Harper's Magazine*, March, 1942.

"The Fight Against T. B." Louise Fox Connell. *You Magazine* (Spring issue), 1942.

"Advice to Pregnant Husbands." Eileen Wilson. *Coronet Magazine*, April, 1942.

(The above is not presented as a complete list and the articles cited are not necessarily recommended.)

FOR SAFER HOMES AND FARMS

The National Safety Council recently held a special conference in Chicago on farm and home safety. The meeting was called in recognition of the increas-

ing gravity of accidents in these fields generally, and also because of the importance of home and farm accident prevention in the present national war emergency.

Of special interest to workers in the public health field was the recognition, at this conference, of the part that can and should be played by health departments, nursing agencies, and similar professional health groups in studying home accident factors, and in exercising preventive measures. Reports were presented indicating the importance of nursing contacts in the home and the use of personal hygiene educational technics, as developed by health departments, in the control of home hazards.

It is also significant to note that the American Public Health Association, the New York State Department of Health, and other health agencies were officially represented at this conference. Plans were perfected for an emergency program, aimed at accident control, especially for smaller communities and rural areas where full-fledged safety movements with paid executives are not practicable. The National Safety Council recognized its responsibility in enlisting the coöperation and aid of numerous agencies able to contribute to the solution of this problem, including the Boy Scouts, the Girl Scouts, the Red Cross, Chambers of Commerce, Departments of Agriculture, and the like. To an increasing extent it may be expected that health agencies, official and voluntary, will be called upon to participate more actively in education as to home and farm safety.

In fact, the New York State Department of Health has already taken initial steps toward the development of an educational program to combat such accidents. At a recent conference held in Albany, representatives of practically all official and voluntary agencies of the state concerned with accidents, agreed that a program should be worked out.

Public health nurses are to play an important part in the proposed educational campaign.

JOTTINGS

The *New York Times* recently commented on the growing tendency of factory managers to distribute vitamin pills to workers. The paper, after deploring "the vitamin craze" in general, remarked that "the nutrition expert should determine when vitamins are to be administered—not a well-meaning, but uninformed, factory manager." . . . Watch for the appearance of "Vital Victor," a cartoon character that may become the symbol of good nutrition. His body is constructed of various food products. He is a rather ingenious little fellow and will probably catch the public's fancy. . . . A quotation from *The Lancet*, the British medical journal: "Two sorts of scientists speak from public platforms: those who think they have something to say and those who think they have to say something." . . . If optimum health and cleanliness go hand in hand, then there's comfort in knowing that last year the 76 members of the Association of Soap Producers, representing about 40 per cent of the nation's production, had sales amounting to \$326,133,270! . . . It is predicted that as cuffs disappear from men's trousers, the number of injuries due to falls will sharply decline. In the thirty-odd years that cuffs have been fashionable they accounted, it is believed, for 93 per cent of all male falls downstairs, including 52 per cent for which Demon Rum got the blame. . . . Two recent books that are all well worth reading: (1) *The Men Who Make the Future*, by Bruce Bliven, and (2) *Science Year Book of 1942*, by J. D. Ratcliff. Mr. Bliven's book is an engrossing account of the amazing scientific discoveries that are now taking place in medicine, surgery, chemistry, and other fields. Mr. Ratcliff's book is a straightforward

summary of scientific advances in the past year, written in the author's usual lively style. . . . Do you enjoy a literary adventure now and then? If so, read "Soliloquy to Balance the Budget," a radio play by Norman Corwin. We recommend it here particularly because of Corwin's masterful description of the human brain and its functions. The play is found in a collection of radio dramas published by Henry Holt and Company under the title "Thirteen by Corwin." . . . If there are any readers of this section of the JOURNAL who have not yet seen the "Fitness for Freedom" issue of *Survey Graphic* (published in March), we suggest securing a copy. This excellent number was planned "to spread the gospel of health" and no public health worker should miss it. Much of the material in this special issue could be used advantageously in preparing speeches for the general public. . . . One of the country's leading poster artists says: "The poster field is a very special one and involves difficulties and problems unlike those encountered in other art forms. So much depends on terseness and absolute clearness. Ideas must be instantly communicated or they are likely not to get across at all. The poster must be designed to be read by him who runs. Thus it becomes a matter of presenting a single idea with such arresting forcefulness that a mere swift glance on the part of the spectator suffices. When a poster fulfils these requisites, it rings the bell." . . . Quotation from Grace T. Hallock: "The final stages of a campaign against a disease are always the hardest because enthusiasm wanes when a cause is almost won. If we forget what an ebbing menace was like when it was at the flood, we may neglect the precautions which will keep it from rising once again. Perhaps that is one of the chief services of history—to keep a memory green until a task is done."

BOOKS AND REPORTS

Handbook for Civilian Defense—
By H. Mayer-Daxlanden. *New York: Civilian Advisory Service* (41 Park Row), 1941. 88 pp. Price, \$1.00.

In a preface the author of this timely handbook tells us he came to its writing "consumed with apprehension" after studying civil defense in Europe and nearly 20 years of publishing on industrial hygiene and accident prevention. His handbook is an elementary one, almost devoid of technical language and designed in good spirit to assist the novice who volunteers as a civilian defense worker in these days of potential blitz warfare on the home front.

Almost at once the text jumps into the matter of incendiary bombs and fire control, and from there rather abruptly to the air raid warden service, and thence in a series of loosely connected paragraphs it covers about all of the recognized civil defense activities, or, as the British would have it, Air Raid Precautions (ARP) services. Nearly 20 of the 88 pages are devoted to chemical or gas warfare from the civilian viewpoint, and who can tell whether this is too great emphasis? In the air raid warden portion we find an essential doctrine set forth that is gradually gaining adequate acceptance in the United States, namely that *all* civil defense personnel should have theoretical training, followed by practical drilling in the field in order to establish familiarity with vital duties through practice. "Each service must have its own detailed instruction but an air raid warden must understand the basic principles of all the work."

Air raid warnings, control and report centers, shelters, first aid posts and medical services, rest and feeding and

nutritional branches of civil defense, and a host of allied welfare responsibilities—these fill the short and longer paragraphs in a rather disjointed manner in the handbook which at first disappoints by its lack of order and balance in the discussion of the various topics. In the end, however, the reading has been stimulating and should lead to a desire to know thoroughly the first text in the bibliography, that best American reference *Civil Air Defense*, by A. M. Prentiss, Lt. Colonel, U. S. Army. In this connection, mention should perhaps be made of the more recent publications of the U. S. Office of Civilian Defense, the *Handbooks*, *Textbooks*, *Planning and Training Guides*, and *Bulletins* which can be secured by the interested civilian through his local defense council, and of the British Library of Information, 30 Rockefeller Plaza, New York, N. Y., which is the American source for all official British publications including ARP and the related Emergency Medical Services. And, finally, no one should miss John Strachey's classic eye and ear-witness description of the London blitzes he went through as a warden, entitled "Digging for Mrs. Miller." HUNTINGTON WILLIAMS

Behind the Mask of Medicine—
By Miles Atkinson. *New York: Scribner*, 1941. 348 pp. Price, \$3.00.

This is not just another book. The author says that it is not easy to explain in a few words the idea he had in writing it, but that it "represents an attempt to find out where and how we have gone wrong." He believes that we have gone wrong in more ways than one.

The twelve chapters are systemati-

cally arranged, and contain a wealth of information, much of which is intended for the public, but all of which should be better known to the medical profession than is the case. He glories in the achievements of the medical profession but does not hesitate to point out its weaknesses. He emphasizes the social side of medicine and declares that it is not only a social science, but "perhaps the most important of them all." He follows the historical method, believing that a study of the past provides our only safe guide for the future.

The phenomenal progress made during the last hundred years has come like "a thunderbolt of knowledge which knocked away the props that had stood for two thousand years and more." We have not had time to digest what has come to us, and medicine, like the rest of the world, is in something of a turmoil. The author emphasizes reverence for the profession, its accomplishments, standards, and aims, holding that without the knowledge we owe to medical science we would revert inevitably to the darkness of the Middle Ages. As a basis for this belief the first two chapters are devoted to history and are well done. Later chapters speak of the problems which the doctor is constantly up against, beginning with diagnosis. As presented, they constitute really a study of human nature as the doctor sees it in practice. This necessarily brings in the fads and follies, for some of which the doctor is responsible, such as too much specialism, excesses in surgery, quacks, fee-splitting, etc.

The discussion of euthanasia which comes in the chapter "The Art of Prophecy" (prognosis) is one of the best. The chapter, "Tradition in Medicine" is striking. As a graduate of "Barts," the only hospital remaining within the boundaries of the old city walls of London, the author naturally turns to the tradition of that hospital

as an outstanding example, and says that no member of the staff ever violates it and puts private practice before the hospital. He says, "It is in my blood. That is the way with tradition."

The author deplures most of the trends of modern medicine, attributing them to the machine age, which though producing better end results, has done great damage to the physician. He insists that nothing can take the place of the old physician, the personal diagnosis arrived at by careful observation, and the comfort given the patient, even when the outlook is the worst. One can often tell as much with a trained finger—"tactus eruditus" of the old school—as with an electric gadget. To illustrate this point, he tells the story of Sir James McKenzie, who as a busy general practitioner among poor patients and with the simplest of equipment, founded modern cardiology. To his dying day he maintained the advantage of clinical methods over the machine.

The book ends with a forecast which is pessimistic, though the author denies it, and calls himself an optimist. While he believes that our present civilization ended in June, 1940, with the "fall of France and the end of the amazing century," he holds that even if our present civilization dies it has left a record of great strides in the 600 years of its life, and will hand to the next civilization "a tradition of scholarship worthy of that which Greece and Rome bequeathed to it. . . . Medicine may even prove to be the link that will join the old age to the new."

A historical error is found on page 28, where the discovery of the agency of the mosquito in the transmission of yellow fever is attributed to General Gorgas instead of to Walter Reed. General Gorgas was not connected with the Commission, directly or indirectly, and in fact was very slow to accept its findings.

It is hard to speak too highly of this book. Unquestionably there will be disagreement with some of the statements made and grounds taken, but on the whole the author inculcates the highest standards of conduct under every circumstance which may confront the doctor either as a physician or man. We hope for the book a wide reading, not only among the laity but among doctors, especially those entering practice. MAZŸCK P. RAVENEL

Modern Sanitary Engineering—
By G. Eric Mitchell. Brooklyn, N. Y.: Chemical Publishing Co., 1942. 166 pp., diagrams, tables. Price, \$5.00.

A presentation of current British practice in the drainage and sanitation, ventilating, and heating of buildings from foundation to completion, and water supply. Although of use to municipal surveyors and architects, the entire field of sanitary engineering as usually treated in American books is not covered. Plumbing is discussed at some length as are British by-laws with respect to water supply.

ARTHUR P. MILLER

The Essentials of Occupational Diseases—
By Jewett V. Reed and A. K. Harcourt. Indianapolis: Thomas, 1941. 225 pp. Price, \$3.00.

The necessity for the maintenance of man power in the present war emergency makes a volume on the subject of the occupational diseases very timely. In fact, the American literature has been sorely deficient in this respect for many years.

The present volume is very logically arranged and includes sections on poisons, physical agents, skin lesions, pulmonary occupational diseases, occupational malignant diseases, occupational infection, and functional disturbances associated with occupation. Judged by the table of contents, the present volume must be considered

very satisfactory. It is, however, a small book, 225 pages in all, including the bibliography and index, and because of the large field which it covers the presentation of each individual subject is exceedingly brief. For example, 79 chemical poisons are discussed in 100 text pages. It is easy to see that each individual poison must of necessity receive very scant treatment, so scant, in fact, that the volume must be considered as having a very limited field of usefulness. This same criticism is valid throughout the whole of the volume. The prevention of the occupational diseases receives no consideration.

The volume closes with a satisfactory pertinent bibliography of 15 pages.

LEONARD GREENBURG

Treatment of the Patient Past Fifty—
By Ernst P. Boas, M.D. Chicago: Year Book Publishers, 1941. 324 pp. Price, \$4.00.

The author discusses those diseases (mostly chronic and mostly those of the cardiovascular-renal system) which predominate in elderly people, giving sound observations based upon his own extensive clinical experience. He furthermore elaborates, wherever possible, upon the different clinical picture or the different treatment needed with elderly patients as contrasted with younger patients suffering from the same diseases. In this he is limited by the inadequacy of our present information on aging rather than by any unfamiliarity with the literature. A chapter is given to the "general management of the aging and aged person." Dr. Boas distinguishes between aging and pathological processes but seems to assume that only the latter offer hope of control.

The book is for the practising physician. It points out that "the physician tends to minimize the importance of a routine health examination." A chapter is then given to general diagnosis and

treatment of the aged. It is not intended as a textbook or as a reference book. Instead it is both a clinical discussion of chronic diseases and an exposition on the treatment of elderly patients. It admirably fulfils its purpose.

HENRY S. SIMMS

Health—Safety—Growth Series:

Gaining Health (Grade V)—By C. E. Turner, Juanita McD. Melchior and Grace Voris Curl. Boston: Heath, 1941. 296 pp. Price, \$.76.

Cleanliness and Health Protection (Grade VI)—By C. E. Turner, Juanita McD. Melchior and Grace Voris Curl. Boston: Heath, 1941. 244 pp. Price, \$.76.

Working for Community Health (Grade VII)—By C. E. Turner, C. E. Burton and Grace Voris Curl. Boston: Heath, 1941. 276 pp. Price, \$.84.

Building Healthy Bodies (Grade VIII)—By C. E. Turner and C. E. Burton. Boston: Heath, 1941. 308 pp. Price, \$.88.

Any health worker wishing to stimulate school administrators to a new interest in health teaching in the schools, or any school man desiring to show health officers or supervising nurses what modern educational practice is offering in the classroom, should investigate this series which has a book for each grade from the 5th through junior high school.

Health educators disagree as to the emphasis to be placed on presenting anatomical and physiological facts. This reviewer believes Turner and his collaborators have struck the happy mean. The functioning of knowledge at home, in school and in the community is stressed. And the facts are expressed in vocabulary which does not belong to the physiologist or doctor but to the child's own age level. Over and over stress is placed on how to make the best use of everything you have in order to get what *you* as an individual want

out of life. The story telling technic is not overdone. It is so extremely well done in fact that in the last of the series one wishes for more.

The high points of this series are: (1) Each book has a fresh approach adapted to the grade level; (2) the organization of the materials makes them adaptable to various teaching methods; (3) the books are rich in objective material for testing knowledge and behavior, as well as giving an opportunity for original work; (4) the classroom background within which the series was developed has contributed a simplicity of approach that is often lacking in other readers; (5) the standards of accuracy are high; and (6) the carefully prepared word-list for vocabulary building in each book is a fine teaching device.

Among the excellent series of health readers made available during the past year this set is further distinguished for successfully attaining that difficult quality of talking directly to children instead of *about* them. They are friendly books and pupils will like them.

DOROTHY B. NYSWANDER

The Baker Memorial, 1930-1939—
By Haven Emerson, M.D. New York: Commonwealth Fund, 1941. 75 pp. Price, \$.50.

After many years of preliminary discussion and planning the Baker Memorial, "dedicated to the care of people of limited means," admitted its first patients in March, 1930. It was made possible by gifts amounting to \$1,900,000 plus contributions by the Julius Rosenwald Fund and the Baker Memorial, parent institution, the Massachusetts General Hospital, to meet operating deficits which during the first 9 years and 10 months of operation amounted to \$387,150.60. This was exclusive of depreciation and interest. The years 1938 and 1939 each showed a small operating surplus. The average

daily census of patients increased from 87 in 1930 to 208 in 1939 and the percentage of beds occupied, from 54 per cent in the former year to 86 per cent in the latter.

The average Baker Memorial patient had an annual personal income between \$2,000 and \$2,500; he remained in the hospital 13.4 days; he paid \$66.06 for professional services, and for hospitalization expenses, \$119.09. Thus his hospital experience cost him about 8.5 per cent of his annual income. In 1939 the 300 doctors who had patients under their care in the Baker Memorial received from them an average of \$1,290 in professional fees, all of which are collected by the hospital in behalf of the doctors.

That the Baker Memorial has won the approval of that segment of the population it was intended to serve seems clear from its steady growth, from its increasingly satisfactory financial experience, and from the testimony of its patients. Ten questions were sent to 1,766 patients; 943 replied; with only unimportant exceptions the patients who replied were well satisfied with their hospital experience.

The support and approval of the physicians of the Boston area, both those on the closed staff and those without the privilege of taking care of their patients in the hospital, seems to have been nearly unanimous. A minority of the staff were dissatisfied with the inclusive medical fee of \$150; this provision was accordingly somewhat relaxed after 1938 in instances in which patients remained in the hospital more than 3 months.

The theories, policies, and practices of the Baker Memorial provide much helpful material for other communities considering an attempt to provide adequate medical care for the economic group between ward patients and private patients. But it is not irrelevant to point out that the Baker Memorial

was founded under circumstances hard to duplicate. It has had generous financial backing; its parent hospital is one of the great institutions of clinical investigation and teaching; many of the professional staff are distinguished leaders in their fields of work, their professional standards are high, and many have reputations which inevitably would draw patients to the hospital.

In this interesting report Dr. Emerson has made available data accumulated during the first 10 years of the Baker Memorial experience. His approach has been quantitative and his emphasis, like that of nearly every one who writes on problems of medical care, has been on the economic and administrative problems. In these areas his analysis is clear and comprehensive. One could wish that he had extended his analysis to the quality of medical care at the Baker Memorial. A study of the care and completeness with which the patients' records are kept; the percentage of autopsies; the attendance at autopsies; the discrimination with which the laboratory facilities are used; the promptness with which diagnostic and therapeutic discoveries of proven value are adopted; and other similar criteria of quality would have been of great interest. Also an analysis of the Baker Memorial as an educational influence might fittingly have been included. Information on such aspects of a hospital's social responsibilities as staff meetings, educational opportunities for interns and residents, pathological conferences, library facilities, and, not least in importance, the educational influence on the physicians of the Boston area who refer patients to the hospital but are not on the staff, would have been appropriate. G. M. MACKENZIE

How to Prevent Goiter—By Israel Bram. New York: Dutton, 1941. 182 pp., 21 ill. Price, \$2.00.

This small volume is divided into 17

short chapters. The author states that the book is for the purpose of enlightening the public on diseases of the thyroid. The two principal disease groups (1) simple goiter and (2) exophthalmic goiter, are conservatively discussed, and no attempt is made to confuse the reader by reviewing the many other associations of goiter, which the author could have done by stating that goiter is a symptom rather than a disease.

The headings of some of the chapters, as for example "The Healthy Thyroid," "The Unhealthy Thyroid,"

and "What and When Is a Goiter?" may make these chapters more salable but one wonders whether such conservative chapter headings as "Normal Thyroid," "Abnormal Thyroid," and "What Is Goiter?" would not have had just as much appeal with less of the tabloid features of journalism.

The desirability and even purpose of such books may be questioned. Not enough is known by experts in this field to present any comprehensive and simple picture for laymen and, as always, a little knowledge may be a dangerous thing. DAVID MARINE

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Something New Under the Sun—A census of the sewerage systems and disposal methods in the several states. The report shows very substantial progress in the treatment of community sewage. In five states the percentage of the population now served approaches 90. Raw sewage however is still a first class sanitary hazard in many, many sections of the country.

ANON. A Summary of Census Data on Sewerage Systems in the United States. Pub. Health Rep. 57, 12:409 (Mar. 20), 1942.

A Word to Wise Child Hygienists—As tonsillectomy may be done at any time of year, it appears inadvisable to have this operation performed during the poliomyelitis season. Avoiding tonsillectomies then would probably eliminate many cases of the grave and highly fatal bulbar form.

ANON. Tonsillectomy and Poliomyelitis. J.A.M.A. 118, 12:980 (Mar. 21), 1942.

Odd Items from Everywhere Department—National rose hip tea is now on sale (in England), one teaspoonful being sufficient to supply the daily vitamin C need of a child. Plans are under way for the collection of another 200 tons of rose hips on a nationwide scale by teachers, children, *et al.* to be converted into syrup, by selected firms, for use by young children.

ANON. Editorial Notes. J. Roy. Inst. Pub. Health & Hyg. 5, 2:27 (Feb.), 1942.

Ammunition for Health Educators—Nutritionists especially will be interested in these two papers, one reporting upon experimental animals, the other on patients. Together they leave

no doubt but that a vitamin C deficiency decreases the tensile strength of healing wounds. Normal healing may be produced by adequate vitamin C intake postoperatively.

BARTLETT, M. K., *et al.* Vitamin C and Wound Healing. New Eng. J. Med. 226, 12:469 (Mar. 19), 1942.

Reemployment of the Tuberculous—Though there is no evidence that contact with the tuberculous can reactivate quiescent lesions in an employee, the compensation commission's hypothesis that such exposure does reactivate old lesions (therefore tuberculosis in an ex-patient employee is compensable) has caused hospitals to discontinue the employment of ex-patients. This is hurtful both to the institutions and the rehabilitated ex-patients.

BRAHDY, L. Arrested Tuberculosis and Hospital Employment. J. Indust. Hyg. & Toxicol. 24, 3:53 (Mar.), 1942.

Effective Lay Participation—With professional guidance, lay groups can (1) stimulate adequate health services, (2) support competent officials, (3) obtain appropriations, (4) develop widespread understanding of administrative projects, (5) carry on health educational programs. Ways by which they can be organized and guided is the meat of this excellent paper.

BUCK, C. E. The Citizen's Role in Public Health. Pub. Health Nurs. 34, 3:129 (Mar.), 1942.

Premarital Tests—Through the six years of their enactment, some weird premarital legislation has been written

upon the law books, and the 1941 crop succeeded in adding confusion to the existing diversity of procedures. A uniform law, and reciprocity, would add to the undoubted value of this legislation.

FORSTER, G. F., and SHAUGHNESSY, H. J. Premarital Examination Laws in the United States. *J.A.M.A.* 118, 10:790 (Mar. 7), 1942.

Serious Answer to Nutritional Doubts—Evidence presented here that dietary inadequacies and malnutrition are of frequent occurrence in these United States, and that the nutritional status of an appreciable part of the population can be improved, should be studied by any health worker who may have been impressed by the repeated insistence of one of our widely read medical publicists that malnutrition is seldom seen in the celebrated clinics of the country.

JOLLIFFE, N., *et al.* The Prevalence of Malnutrition. *J.A.M.A.* 118, 12:944 (Mar. 21), 1942.

All about Soap—An answer to almost any question one might raise about soaps and the newer sulfonated detergent products will be found in this extensive review of the subject. Sanitarians will be particularly interested in the discussion which leads to the conclusion that mechanical removal of pathogenic organisms from the skin by the emulsification of resident insoluble oils, plays a greater rôle in "sterilization" through scrubbing, than by the actual germicidal action of the detergent used.

LANE, C. G., and BLANK, I. H. Cutaneous Detergents. *J.A.M.A.* 118, 10:804 (Mar. 7), 1942.

Flea- vs. Louse-borne Typhus—Evidence is presented to show that in China, as in Mexico, flea-borne typhus may exist alongside the louse-borne disease, and that epidemics may originate from sick rats. Whether all modern

epidemics spring from rodent reservoirs cannot yet be answered.

LIU, W. T., *et al.* Typhus Fever in Peiping. *Am. J. Hyg.* 35, 2:231 (Mar.), 1942.

Public Health Takes on a New Urgency—Here is a brief summary of the Public Health Service's increasing wartime activities in caring for an augmented merchant marine, an ever-expanding industrial population, civilian health problems in war industry areas, and the vicinity of cantonments. This is a total war, we need often to be reminded.

PARRAN, T. Wartime Problems of the Public Health Service. *J.A.M.A.* 118, 13:1033 (Mar. 28), 1942.

Immunology of Viruses—There is reason to believe that in those virus diseases which confer lasting immunity, the virus establishes itself permanently in, and lives happily with, the body cell. In those diseases like the common cold, the superficial cells carrying the virus are thrown off to be replaced by new, and unaffected cells, and immunity is thus made temporary indeed.

RIVERS, T. M. Immunity in Virus Infections. *Science* 95, 2457:107 (Jan. 30), 1942.

Apparent Failure for Influenza Vaccine—Your attention was called in an earlier bibliography to the introductory part of an exhaustive study upon influenza immunization. The last chapter is now published, and with it the conclusion that as employed in these studies, influenza virus vaccines failed to reduce the incidence of illnesses related to influenza A or any acute respiratory diseases.

SIEGEL, M., *et al.* A Study in Active Immunization against Epidemic Influenza and Pneumococcus Pneumonia at Letchworth Village. *Am. J. Hyg.* 35, 2:186 (Mar.), 1942.

After the Fury Subsides—Do you remember all the dire forebodings

raised by the viewers-with-alarm when premarital blood tests were proposed? Well, after 6 years of experience, the first state to impose this dreadful incentive to immorality on its helpless population finds that marriages have increased, that illicit sex relations have not been encouraged, and that, instead, the law has proved an important method of discovering syphilis, a protection to the innocent, a means of encouraging adequate treatment, a potent preventive of congenital syphilis, and a law of enormous educational value.

TALBOT, H. P. Six Years of the Premarital Blood Test Law in Connecticut. *Monthly Health Bull. (Connecticut)* 56, 3:62 (Mar.), 1942.

More about Cancer in the South—In Birmingham nearly half the white male cases were skin cancer, a proportion higher than in any other city in

the series reported upon. Of the white female cases a third were genitourinary, a quarter were skin, and a fifth were breast cancer cases. There is much else in the report of interest to all health workers.

SOMMERS, H. J. The Incidence of Cancer in Birmingham and Jefferson County, Alabama, 1938. *Pub. Health Rep.* 57, 11:377 (Mar. 13), 1942.

For Your Housing Problem—Are you interested in employing a yardstick for the measuring of housing conditions to guide inspection and enforcement programs? Here, then, is an item upon the technic which might be employed by a local agency on a sampling basis or for a whole substandard area.

TWICHELL, A. A., and SOLOW, A. An Appraisal Technique for Urban Problem Areas as a Basis for Housing Policy of Local Governments. *Pub. Health Rep.* 57, 9:285 (Feb. 27), 1942.

CORRECTION

Correction for page 154, paragraph 1, last sentence, *American Public Health Association Year Book, 1941-1942*
Substitute the following:
In view of the difficulties in classifying

hemolytic streptococci according to serologic type, it was recommended, by implication, that typing not be included in routine practice until the procedures have been perfected.

 Martha Tracy, M.D., Dr.P.H., Philadelphia,
 Pa., Elected Member 1940, Health Officers
 Section

PROGRESS ON MERIT SYSTEM PROJECT

THE membership will be interested in knowing of the progress being made by the Committee on Merit Systems, a subcommittee of the Committee on Professional Education. It will be recalled that the Association was asked by the Children's Bureau and the U. S. Public Health Service to assist in the development of merit systems in the several states. Funds for the first year's work have been provided by several states.

With the able assistance of Milton Rose, M.D., formerly Professor of Public Health at the University of Pennsylvania, the committee has developed a file of examination questions as recently used, and studies have been carried out to discover the best ways of adapting modern methods of personnel selection to the public health field. Dr. Rose has now been called to the West Coast to serve with the American Red Cross. The committee has been fortunate in securing temporarily the services of Dorothy Deming, R.N., formerly Director of the National Organization for Public Health Nursing, who is serving as subject matter consultant in the field of public health nursing. As a specialist in test construction the services of Cecil Brolyer have been loaned temporarily by the Children's Bureau. Mr. Brolyer has had a long experience in the field of test construction with the Children's Bureau and the Social Security Board.

Among the needs felt by the several states, that for items in public health nursing is most urgent and the committee has therefore gone ahead on this phase of its work. Under the general direction of George H. Ramsey, M.D., Dr.P.H., Chairman of the subcommittee, a plan has been evolved to use twenty younger public health nurses for test construction. A series of 4 evening lectures on the rudiments of test con-

struction have been given these nurses, who have purposely been selected from among those in junior positions and among those actively engaged in field work in the belief that their knowledge of actual conditions will best fit them to act as subject matter consultants. At the conclusion of this course the nurses have begun the production of objective type test items which are then cleared through a group of senior public health nurses in positions of instruction or administration who act as members of a final jury. The questions, or items as they are called in this field, are then assembled in a reserve from which, on request, examinations will be constructed for the use of state merit system councils.

In a similar way it is expected that test construction can be carried out in other fields, using specialists from these fields as test constructors under the guidance of a qualified test technician. The resulting examinations it is expected will serve to appraise the abilities and knowledge of applicants as adequately as any tests can accomplish this purpose with our present knowledge.

PUBLIC HEALTH NURSES

THE Merit System Committee of the American Public Health Association is experimenting with certain possible types of items for future use in examinations for public health nursing positions. The committee will have room 788 at the Palmer House, Chicago, during the Biennial Convention, May 18-22, and would appreciate having as many nurses as possible take these tests in order that some preliminary information may be obtained regarding the usefulness of these types of items. Nurses may take the tests anonymously and will be given their scores, but no interpretations can be attached to the scores.

APRIL MEETING OF THE COMMITTEE ON PROFESSIONAL
EDUCATION

ALL the members of the Committee on Professional Education were present at the meeting on April 17 in New York with the exception of Dr. John E. Gordon who is in England. The committee unanimously adopted a Memorandum presented by Dr. W. P. Shepard of San Francisco, *Chairman*, regarding the Minimum Educational Facilities Necessary for the Postgraduate Education of Those Seeking Careers in Public Health, which is published in this issue. This Memorandum should be of immediate use to teaching institutions, appointing bodies, and candidates for professional careers in public health. It reflects the variety of educational resources which are essential for the proper training of persons in various specialties of public health. The committee hopes that it will serve to direct attention to excellent facilities that are available and make less likely the development of courses under auspices which, in the nature of the case cannot be regarded as adequate, even in the emergency.

George H. Ramsey, M.D., Chairman of the Subcommittee on Merit Systems, presented a report of current activities which is summarized on page 559.

The Committee on Professional Education adopted a simplified outline for handling future reports covering the training and experience of persons engaged in public health and approved a routine for handling these reports and maturing them into official declarations of the Association.

A preliminary report on the Educational Qualifications of Health Educators prepared by the subcommittee of which Clair E. Turner, Dr.P.H., is Chairman, was received by the committee. This report will replace the one on the Educational Qualifications of School Health Educators which was

previously approved by the Governing Council. The Executive Board will be asked to authorize the withdrawal of the earlier report from circulation, since it has already served its usefulness. Because of the demand for a statement on qualifications of health educators, the committee authorized the distribution of the new report in its preliminary form to interested individuals.

Ralph E. Tarbett, C.E., Chairman of the Subcommittee on the Educational Qualifications of Professional Personnel in Sanitation, reported that there was under way reconsideration of the subcommittee's report, having in mind the comments of the Conference of State Sanitary Engineers and others on the subject.

Other subcommittees having reports finally approved and published, presented statements which were considered. These dealt with the educational qualifications of health officers, public health nutritionists, industrial hygienists, public health statisticians, public health nurses, and public health nurses in industry.

New reports from subcommittees were received on the educational qualifications of laboratory personnel, maternal and child health specialists, professional workers in mental hygiene, specialists in cancer control, venereal disease control officers, and public health dentists.

For purposes of the committee's work, professional education has been defined for the time being to mean public health training at the graduate level, or that subsequent to basic or legally recognized professional training. The committee does not overlook the importance of sub-professional levels but recognizes that the problems of this group are so different from those of the professional worker that

they must be separately considered.

Interesting reports were received from Lowell J. Reed, Ph.D., representing the Association of Schools of Public Health, and from Harry S. Mustard, M.D., representing the Association of American Medical Colleges, in relationship to the teaching of public health. Consideration was also given to the budgetary provision being made for the emergency training of public health workers and supplemental funds available through various channels for physicians, dentists, public health nurses, and engineers, under the provisions of accelerated training.

It was decided to provide for a subcommittee on the educational qualifications of school physicians and for a subcommittee on qualifications for

secretaries of voluntary health agencies.

The members of the Committee on Professional Education present included William P. Shepard, M.D., *Chairman*, Reginald M. Atwater, M.D., *Secretary*, Edward S. Godfrey, Jr., M.D., Ira V. Hiscock, Sc.D., George H. Ramsey, M.D., Lowell J. Reed, Ph.D., Wilson G. Smillie, M.D., Ralph E. Tarbett, C.E., and Henry F. Vaughan, Dr.P.H. In addition, guests included John L. Rice, M.D., President of the Association, Huntington Williams, M.D., member of the Executive Board, Harry S. Mustard, M.D., Editor of the *Journal*, Mary J. Dunn, R.N., representing Pearl McIver, R.N., a member of the committee, Benjamin G. Horning, M.D., W. D. Stovall, M.D., and Clair E. Turner, Dr.P.H.

Health Conservation Contests' National Health Honor Roll

WINNERS IN THE 13TH ANNUAL CITY HEALTH CONSERVATION CONTEST

Detroit, Mich.
Evanston, Ill.
Greenwich, Conn.
Hackensack, N. J.
Hartford, Conn.
LaSalle, Peru, Oglesby, Ill.
Louisville, Ky.
Madison, Wis.
Memphis, Tenn.
Milwaukee, Wis.
Newton, Mass.
Racine, Wis.
Reading, Pa.
Schenectady, N. Y.

WINNERS IN THE 8TH ANNUAL RURAL HEALTH CONSERVATION CONTEST

Alger-Schoolcraft Counties, Mich.
Arlington County, Va.
Davidson County, Tenn.
Fayette County, Ky.
Forsyth County, N. C.
Gallatin County, Mont.
Gibson County, Tenn.
Glynn County, Ga.
Lauderdale County, Miss.
Madison County, Ky.
Saginaw County, Mich.
Santa Barbara County, Calif.
Thurston County, Wash.
Whitman County, Wash.

These Contests are conducted annually by the Chamber of Commerce of the United States with the coöperation of the American Public Health Association. The Rural Health Conservation Contest is financed by the W. K. Kellogg Foundation, and the City Health Conservation Contest is financed by the Metropolitan Life Insurance Company.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y.

ARIZONA MERIT SYSTEM COUNCIL

The Merit System Council for the Arizona State Department of Social Security and Welfare and State Department of Health will probably shortly announce merit examinations for positions in those departments as follows:

State Director, Local Health Administration.....	\$350-400
Director Maternal and Child Hygiene.....	350-400
Director, Local Health Unit.....	350-400 and \$300-350
Health Officer-in-Training.....	300-350
Director of Sanitary Engineering.....	300-350
Sanitary Engineer	200-250
Director, Public Health Laboratory.....	300-350
Senior and Junior Bacteriologist-Scrologist.....	165-215 and \$115-165 respectively
X-ray Technician	165-190
Director Public Health Nursing.....	215-265
Nursing Consultant, special fields.....	175-200
Supervising Public Health Nurse, local unit....	175-200
Senior and Junior Public Health Nurse, local unit	150-175 and \$125-150 respectively
Public Health Nurse-in-Training.....	100-125
Director Health Education.....	215-265
Nutrition Consultant	215-265
Vital Statistician	175-225
Medical Social Worker.....	165-190
Child Welfare Consultant.....	200-250

Competition is open on a nation-wide basis. Professional registration in Arizona required before appointment for certain classes. Closing date for receipt of applications will probably be about June 15.

Application blanks, information regarding qualification requirements, conditions governing filing of applications, and detailed descriptions of the various classes of positions may be secured from the Merit System Council, Room 208, Home Builders Building, Phoenix, Ariz.

GEORGIA STATE MERIT SYSTEM ADMINISTRATION

The Supervisor of Examinations of the Georgia State Welfare Department announces competitive examinations for filling positions in the Public Assistance, Crippled Children, and Child Welfare Divisions. In the Crippled Children Division the salary ranges are minimum \$1,800, maximum \$2,280 for the position of Medical Social Worker, Orthopedic Field Nurse, and Physical Therapy Technician; for District Orthopedic Field Nurse a minimum of \$1,920, maximum of \$2,400; Physical Therapy Consultant a minimum of \$2,400, maximum of \$2,880; Orthopedic Nursing Consultant and Medical Social Consultant begin at a minimum of \$2,700 and range to a maximum of \$3,180; Medical Director of the Crippled Children Services begin at a minimum of \$4,200 with a maximum of \$5,400.

All of these positions are open to competitive assembled examinations except the Medical Director of the Crippled Children Services which is an unassembled examination. The examinations are based upon a rating of training and experience, a written test, and an oral interview. Each eligible who is appointed from the adequate register will be required to serve a probational period of 6 months as is the usual custom in Civil Service and Merit System agencies.

Georgia State residence is not required of an applicant in order to participate in the above examinations.

U. S. CIVIL SERVICE COMMISSION

The Commission has announced unassembled examinations for Junior Public Health Nurse at \$1,800 a year and Junior Graduate Nurses at \$1,620 a year, under which the training and age requirements of announcements No. 88 and 103 of 1941 have been amended. Persons interested should communicate with the U. S. Civil Service Commission in Washington or obtain the amended announcements at any first or second class post office.

The Commission announces unassembled examinations for Home Economists in 5 different grades at \$2,600 to \$5,600 a year. Interested persons should apply to the Commission for Circular 195 on Home Economics.

PHYSICIANS NEEDED IN CANAL ZONE

The U. S. Civil Service Commission announces an examination to secure physicians for clinical service in the Panama Canal Zone. Graduation from a class A medical school subsequent to May 1, 1920, is required, and the applicant must be under 50, 25 to 35 years of age preferred. Entrance salary \$4,000. Persons interested should communicate with the U. S. Civil Service Commission, Washington.

POSITIONS AVAILABLE

Physician with either public health training or experience in local health department administration to serve as health director in a county health department in mid-western state. Salary \$4,000 and \$500 travel (flat rate). Well established department with offices in attractive little city of 10,000. Write Box T, Employment Service, A.P.H.A.

Wanted: Trained Public Health Nurse, starting salary \$1,500 per year and traveling expense, increase to \$1,620 within 6 months. Saginaw County Health Dept., Saginaw, Mich.

Western state department of health will consider applications from physicians to fill four existing vacancies among county health officers, one vacancy in venereal disease control and positions as laboratory technicians. Write Box S, Employment Service, A.P.H.A.

County Public Health Nurses for New Mexico. Must have four months' post-graduate instruction under one of the recognized public health nursing courses and one year's experience. Must drive and have a car. Address inquiry to State Health Department, Santa Fe, N. M.

PUBLIC HEALTH ENGINEER

Responsible professional public health engineering involving field investigations and office studies in the application of sanitary measures. The more difficult engineering and sanitation field surveys include supervision over public water supplies, sewerage systems and sewage treatment plants and review of plans for same, and promotion and supervision of sanitation programs. Minimum qualifications: Training and experience equivalent to 3 years' civil engineering experience, includ-

ing 2 years in public health or sanitary engineering; or completion of an academic year of graduate study and a year's experience in sanitary or public health engineering; and graduation from a college of recognized standing with a major course in civil or sanitary engineering. The salary range is \$205 to \$250 per month depending upon experience. Apply Box E, Employment Service, A.P.H.A.

OTHER VACANCIES

Southwestern State Health Department seeks 2 physicians for assignment to district health units, personally to conduct several small venereal disease clinics on a rotating schedule. Experience preferred but not required. Salary \$3,000, plus actual travel allowance not to exceed \$1,200. Write Box V, Employment Service, A.P.H.A.

Middle western city, 125,000 population, seeks well trained and experienced Health Officer on full-time, with competence to administer a department and teach public health to medical students. Salary \$5,000 to \$5,500 per annum. Write Box K, Employment Service, A.P.H.A.

The New Mexico State Department of Public Health will consider applications for the position of Assistant Director of the Maternal and Child Health Division and for Dental Health Consultant of that Division; also for the position of Nutrition Consultant. Address inquiries to the State Department of Public Health, Santa Fe, N. M.

Wanted: Trained Public Health Nurse, starting salary \$1,500 per year and traveling expenses. Increase may be expected within 6 months. Shiawassee County Health Department, Corunna, Mich.

Wanted: Nurse for county health work. Salary \$1,800 per year with travel allowance (additional) of \$500 per year. Address District Health Department 2, West Branch, Mich.

Instructor in Bacteriology, Medical School, large midwestern university, M.D. (or Ph.D. or D.Sc. in Bacteriology); Male. Salary \$1,800 to \$2,500 according to age and experience. Write Box D, Employment Service, A.P.H.A.

POSITIONS WANTED

ADMINISTRATIVE

Teaching or administrative position desired by physician, aged 48. Experienced teacher in preventive medicine and public health, now employed at prominent medical school; 20 years' experience in municipal health administration and epidemiology. A-491

Physician, B.S., M.D., and M.S.P.H., University of Michigan, aged 35, experienced city-county health administration and as director university student health service. Will consider permanent responsible position offering good income. A-492

Physician, age 32, 5 years' clinical and administrative experience in venereal diseases, wishes administrative position in venereal disease control, preferably at state level. A-490

Physician, aged 28; M.D. Rush; M.P.H. Harvard; seeks administrative position under first class supervision. A-496

WOMEN PHYSICIANS TRAINED IN PUBLIC HEALTH

Woman aged 34, M.D., University of Basle, Switzerland, M.S.P.H. DeLamar Institute, Columbia University. U. S. citizen. Excellent references. Especially interested in industrial hygiene. A-493

Woman aged 41, M.D. Columbia University, M.S.P.H. DeLamar Institute, experienced in epidemiology and research, seeks position offering administrative experience. A-494

Woman physician, aged 48, M.D., University of Vienna. Excellent European pediatric experience. Seeks position in pediatrics, administration or statistical research. A-495

HEALTH EDUCATION

Teacher and research worker, man, Ph.D., age 52. Extensive record as college professor of biology and hygiene and investigator, for the past two years engaged in research. H-499

Health Educator, Negro, man with background of High School administration and M.S.P.H. from University of Michigan, seeks position in Health Edu-

cation. Public agency or educational field. Excellent references. H-497

Woman, M.S. in public health, excellent graduate training in education, 8 years' experience as business executive (sales and publicity). Just completed year's research in community education. Seeks good administrative position. H-496

Health Educator, M.A. in Education, 10 years' background in community organization for public health education, also teaching of personal and community health at high school and college levels. Public health nurse, able to teach mental and social hygiene as well as general health education. East preferred. H-498

Health Educator. Man with M.S. in preventive medicine and public health. Negro. Seeks position in Health Education or field work with official or non-official agency. H-500

Woman with master's degree in health education, 12 years' successful experience in public school and college teaching, administration and research. Will consider position in normal school, public schools, or in official or nonofficial health agencies. Prefers South or East. Available at once. H-501

LABORATORY

Milk Sanitarian and Technologist, age 37, Ph.D., Bacteriology, Wisconsin, 10 years' experience in milk and food sanitation from industrial and official angle, seeks administrative position with opportunity for research or investigational work preferred. L-381

Chemist, Sc.D., Biochemistry, Johns Hopkins University. Age 31. Public health laboratory experience, teaching experience. Desires position with promise of advancement, preferably in commercial organization. L-461

Bacteriologist, young man 28, with B.S. in industrial science, experienced in newspaper work, salesmanship and now employed in state department of health laboratory, seeks position as bacteriologist or doing promotional work of public health nature. L-465

STATISTICAL

Woman with academic, business and research experience in vital statistics, seeks a position in the vital statistics division of a state or city health department, preferably as registrar. S-459

Experienced and well trained public

health nurse, with background of tuberculosis, venereal disease, school, industrial, and generalized services, will shortly be available for appointment. Three years as director of state nursing service. Experienced as university teacher of public health nursing. M.A., New York University. M-449

Advertisement

Opportunities Available

PUBLIC HEALTH NURSES—(a) Director of nurses for hospital unit in western college; public health training and experience required; \$1,800-\$2,000. (b) Supervisor for Visiting Nurses Association, midwest city; two assistants; car furnished, all expenses; \$1,800. (c) Generalized service; responsibility for public health nursing in schools; \$1,800, liberal mileage allowance; Northwest. (d) Staff nurse for home delivery service; degree, public health certificate required; \$1,800, travel expenses. PH5-1, Medical Bureau (Burnice Larson, Director), Palmolive Building, Chicago.

PUBLIC HEALTH PHYSICIANS—(a) Physician with public health administrative experience;

faculty appointment, university medical school; woman eligible; rank dependent upon qualifications. (b) Woman physician to head department of health, young women's college; South. (c) Pediatrician for interesting position, state public health department; \$4,800, traveling expenses; Midwest. (d) Public health physician; man or woman; if not trained, training provided; state department. (e) Student health physician; state university; opportunity to combine duties with training leading to M.C. in public health. (f) Woman physician to conduct lay educational program in cancer control; considerable traveling; Midwest. PH5-2, Medical Bureau (Burnice Larson, Director), Palmolive Building, Chicago.

Advertisement

Situations Wanted

YOUNG WOMAN PHYSICIAN—Well trained in public health medicine and with successful record as county health officer desires position affording opportunity to specialize in syphilology in which, too, she has had some special training. PH5-3, Medical Bureau (Burnice Larson, Director), Palmolive Building, Chicago.

PUBLIC HEALTH ADMINISTRATOR—Taught bacteriology and basic medical sciences for 5 years after receiving academic degree and before entering medical school; 12 years with a municipal health department during which time he served as director for 7 years; has made many valuable contributions

to professional literature; knows the scientific as well as practical side of public health medicine. PH5-4, Medical Bureau (Burnice Larson, Director), Palmolive Building, Chicago.

BACTERIOLOGIST—Desires to re-locate; B.A., M.Sc., Ph.D. (in Bacteriology), eastern schools; 3 years, bacteriologist, state public health laboratories; past several years, instructor, department of bacteriology, state university; not likely to be called to military service. PH5-6, Medical Bureau (Burnice Larson, Director), Palmolive Building, Chicago.

NEWS FROM THE FIELD

SUMMER SCHOOL COURSES IN PUBLIC HEALTH

While the following list does not show all universities and technical schools offering summer courses in public health, it represents those which have replied to a questionnaire sent out by the American Public Health Association. Subjects covered may be ascertained by writing directly to the schools listed.

University of Alabama, University, Ala.

June 8–August 29

Boston University, Boston, Mass.

July 6–August 15

University of California, Berkeley, Calif.

June 29–August 7

University of California at Los Angeles, Los Angeles, Calif.

June 29–August 7

The Catholic University of America, Washington, D. C.

June 27–August 8

University of Chicago (Department of Nursing Education), Chicago, Ill.

June 23–August 1; August 3–September 12

Teachers College, Columbia University, New York, N. Y.

CONFIDENTIAL REPORT ON BOMBING AVAILABLE

WALTER D. BINGER, Chairman of the National Technological Civil Protection Committee, on his return from England as a consultant to the Secretary of War, has prepared a confidential report on his observations on many of the problems associated with the bombing of cities. In this report he discusses in considerable detail both the effects of such bombing and the administrative and technical practices which have been developed in England to prevent damage as well as to correct the effects of destruction.

The report is not available for general distribution, but a copy has been

placed in the office of the Commanding Officer of each Army Corps Area in the United States. It can be reviewed in that office, by permission of the Commanding Officer, upon request by public officials who have a concern with and are interested in the subjects covered. The report deals with a number of engineering and medical aspects of public health control under wartime conditions. It sheds considerable light upon the problems of maintaining utility service under these conditions of stress.

The American Public Health Association is represented on the National Technological Civil Protection Committee by Abel Wolman, Dr. Eng., Professor of Sanitary Engineering, Johns Hopkins University, and Chairman of the Executive Board, A.P.H.A.

NEW YORK STATE DEPARTMENT OF HEALTH PERSONNEL FOR MILITARY DUTY

MEMBERS of the Medical and Sanitary Engineering staffs of the New York State Department of Health called for military duty, with date of commencing such duty:

Daniel P. McMahon, M.D., District State Health Officer, February 26, 1942

Warren W. Lacey, M.D., Assistant District State Health Officer, April 1, 1941

Malcolm A. Bouton, M.D., Medical Consultant in Social Hygiene, April 13, 1942

Alfred H. Dobrak, M.D., Epidemiologist-in-training, June 1, 1941

Charles A. Agar, Senior Sanitary Engineer, April 1, 1942

Stanley T. Barker, Assistant Sanitary Engineer, November 11, 1940

Robert N. Clark, Assistant Sanitary Engineer, March 30, 1941

Andrew J. Fuller, Assistant Sanitary Engineer, December 30, 1940

Harly M. Riley, Assistant Sanitary Engineer, May 12, 1941

Ralph C. Sweeney, Assistant Sanitary Engineer, May 4, 1941

Lyndon M. Keller, Junior Sanitary Engineer, May 12, 1941

Nicholas Milone, Assistant Milk Sanitarian, April 6, 1942

PUBLIC HEALTH SERVICE LOANS PERSONNEL TO NEW YORK STATE

THE New York State Department of Health announces that 3 physicians and 4 sanitary engineers of the staff of the U. S. Public Health Service Reserve have been loaned to the department for the purpose of providing additional service in regions where the population has been increased because of defense industry activities and military concentrations.

TEN THOUSAND NURSES NEEDED FOR U. S. ARMY

ON March 13 it was announced that the U. S. Army Nurse Corps has immediate need for 3,000 qualified registered nurses and that, before the end of 1942, 10,000 in all will be needed to keep pace with the expanding demands from the Army. Eligible applicants must be of good character, unmarried, citizens of the United States, between 22 and 30 years of age, at least 5 ft. tall, and of standard weight for age and height. Graduation from an accredited high school giving a 4 year academic course and a school of nursing of approved standards is required, together with nursing registration. Applicants who can fulfil the requirements will be appointed to the grade of Nurse with the relative rank of Second Lieutenant. The pay is \$840 a year in addition to maintenance and uniform equipment. Appointment authority for the Army Nurse Corps is vested in the Commanding Generals of the various Corps areas.

NORTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION

THE Northern California Public Health Association elected the following officers at its recent annual meeting in Berkeley:

President—John D. Fuller, M.D., Santa Cruz

President-elect—William A. Powell, M.D., Martinez

Vice-President—Edward A. Reinke, Berkeley

Secretary—Mrs. Ann W. Haynes, San Francisco

Treasurer—Helen Hartley, R.N., Stockton

Representative to A.P.H.A. Governing Council—Fred T. Foard, M.D., San Francisco

Representative to Regional Board of Western Branch—Edith P. Sappington, M.D., San Francisco

SOUTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION

AT a recent annual meeting of the Southern California Public Health Association the following officers were elected to serve for the current year:

President—Roy O. Gilbert, M.D., Glendale
President-elect—A. Victor Nasatir, M.D., Los Angeles

1st Vice-President—Charles W. Arthur, Pasadena

2nd Vice-President—J. F. Kessel, Ph.D., Los Angeles

Secretary-Treasurer—Floyd P. Wilcox, D.V.M., Los Angeles

Assistant Secretary-Treasurer—Alice Rorri-son, Pasadena

DELAWARE PUBLIC HEALTH ASSOCIATION ORGANIZED

AT a recent meeting in Wilmington, the Delaware Public Health Association was organized, with the following officers:

President—Edwin Cameron, M.D., Dover
Vice-President—George H. Gehrman, M.D., Wilmington

Vice-President—Anna Van W. Castle, R.N., Wilmington

Secretary—G. Taggart Evans, Wilmington
Treasurer—Roger Murray, M.D., Wilmington

PROCUREMENT AND ASSIGNMENT SERVICE ROUTINE FOR THE SELECTION OF MEDICAL PERSONNEL

LIEUTENANT COLONEL S. F. SEELEY, Executive Officer of the Procurement and Assignment Service for Physicians, Dentists, and Veterinarians, Washington, D. C., speaking recently in New York City before the Medical Society of the County of New York, described the questionnaires from the Procurement and Assignment Service which were circulated in April to all physicians, dentists, and veterinarians, giving them an opportunity to state their preference should they be called, whether in military, governmental, industrial, or civil activity. Colonel Seeley described the national roster already prepared by the medical and dental professions for this purpose. The following routine has been established:

The selection of professional personnel in these classifications is to be on a voluntary basis as much as possible. To the original questionnaire to physicians sent out 23 months ago, more than 159,000 physicians responded, more than 50 per cent of whom were willing to volunteer for medical service in case of war. Of those under the age of 45 years, 63 per cent of the single physicians and 48 per cent of the married physicians even at that early date were willing to offer their services.

Colonel Seeley advised all physicians interested in knowing where their special experience would be most useful to apply to the Procurement and Assignment Service, Washington, which will be responsible for supplying the needs of the Army, Navy, Public Health Service, Civil Service Commission, Veterans' Administration, and the Children's Bureau, as well as other government services. No service will commission or employ a person unless cleared by the Procurement and As-

signment Service. According to Colonel Seeley, the Navy will need a total of 3,000 doctors when its enlistment of 500,000 is reached. For the Army, 16,000 new physicians must be supplied by December 1. It is believed that there will be no difficulty in obtaining these officers on a voluntary basis without jeopardy to civilian needs.

Explaining how the service will operate, Colonel Seeley said that, when requests came from the Army or the Navy for doctors with special qualifications, these would be sorted immediately by punch cards from the 180,000 cards for physicians, and the names of physicians meeting the qualifications would be listed mechanically by the machine. One copy would go to the military service inquiring, the other would be broken into state lists and forwarded to the state chairmen of Procurement and Assignment to determine whether or not these men can be spared from their communities at present. According to Colonel Seeley, they will not be assigned to duty unless they can be replaced, if they are essential on staffs of teaching instructions, industrial plants, hospital staffs, public health services, or in private practice. It is expected, however, that all these essential positions ultimately can be filled by men over 45 or by those physically unfit for service under that age and by women doctors, of whom the nation now has 8,000 in active practice.

The responsible appointing officer would then get in touch with those specialists who are qualified and willing to serve and who are cleared by the local medical committee. It would then be possible to determine the rank each should receive in a commission, choosing these in consideration of the man's needs and of many other factors to be determined.

Every physician, dentist, and veterinarian who enrolls in the Procurement and Assignment Service will be

given a certificate to hang on his wall and be authorized to wear an insignia on his lapel showing that he has offered his services in his professional capacity to his country to win the war, even though it may be decided that he is needed in his own community.

CONTINUATION STUDY COURSE IN MILK
PLANT OPERATION AT MICHIGAN

THE School of Public Health at the University of Michigan, Ann Arbor, is offering a series of in-service, non-credit training courses of which the first will be a course on May 12 and 13 for operators, owners, and managers of milk pasteurization plants. Other courses planned in this series will provide instruction for individuals employed in public health services, physicians and dentists in private practice, and other professional groups with a major interest in health science services, as well as courses for business, trade, and professional groups whose interests and occupations touch closely the problem of public health, such as hotel and restaurant managers, well drillers, plumbers, health board members, school officials, public works and service officials, probate judges, etc.

A special faculty group brought together for the occasion has been provided for the course for milk pasteurization plant operators. Emphasis will be laid on the health phases and sanitary aspects of the problem. The course is expected to represent a coherent unit of instruction rather than a series of unrelated lectures.

Participants in this course will include Henry F. Vaughan, Dr.P.H., Dean of the School of Public Health, Ann Arbor, James A. Tobey, Dr.P.H., New York, R. S. Breed, Ph.D., Geneva, N. Y., Milton J. Rosenau, M.D., Dean of the School of Public Health, University of North Carolina, Walter D. Tiedeman, C.E., New York State Department of Health, Albany, W. L.

Mallman, Ph.D., Michigan State College, among others. The fee for registration and enrollment is \$5.00. Further information can be obtained from the School of Public Health, University of Michigan, Ann Arbor.

EIGHTH PAN AMERICAN CHILD CONGRESS,
WASHINGTON, MAY 2 TO 9

THE announcement has been made by the U. S. Department of State and the officials of the International American Institute for the Protection of Childhood, Montevideo, that the Eighth Pan American Child Congress will be held as scheduled May 2 to 9 in Washington with a program somewhat revised in consideration of the outbreak of war.

The entry of the United States and certain of the other American republics into the world conflict has necessitated reconsideration of the plans for the Congress in the light of war conditions and the resultant effects upon children. The Organizing Committee has consulted various individuals and organizations in the other American republics, as well as interested groups in the United States and the pertinent departments and agencies of the federal government in order to determine the basis upon which the meeting is to be organized under present circumstances. The committee has reached the conclusion that under war conditions it is even more important than in peace times to proceed with the plans for the promotion of inter-American coöperation in the protection and welfare of children.

It has been decided, therefore, in consideration of all the attendant circumstances to modify the scope and objectives of the Congress with a view to giving special emphasis to measures for maintaining and strengthening essential services to meet wartime needs, and to laying the foundations for closer inter-American collaboration for the protection of childhood in the war and post-war periods.

EXAMINATION FOR ASSISTANT SANITARY
ENGINEERS, U. S. PUBLIC HEALTH
SERVICE

AN examination for appointment as Assistant Sanitary Engineer in the regular commissioned corps of the U. S. Public Health Service has been announced for Washington, D. C., Cincinnati, New Orleans, Kansas City, and San Francisco on May 11. Candidates must be not less than 23 years nor more than 32 years of age and must have had at least 7 years of educational and professional training following high school, or experience equivalent thereto. They must have graduated from a reputable professional school granting a degree in engineering. In addition the applicant will be required to pass a satisfactory physical, academic, and professional examination. Compensation, including allowance for quarters and subsistence, will be \$3,158 and \$2,699 for officers with and without dependents, respectively.

MASSACHUSETTS INSTITUTE OF
TECHNOLOGY

THE Department of Public Health at the Massachusetts Institute of Technology is offering an accelerated program of public health training beginning June 8 and allowing for the completion of a Master's degree on February 6. These training programs are organized for public health engineers, health educators, and public health laboratorians, as well as for administrators. Special summer courses are also being offered.

"HIDDEN HUNGER"

THE Honorable Paul V. McNutt, Administrator of the Federal Security Agency, asks the assistance of public health workers in having the recently released film entitled "Hidden Hunger," which is sponsored by the

Office of Defense Health and Welfare Services, shown in their communities.

The purpose of the film is to help win the war on the food front, and it will soon be shown in theatres from coast to coast. Health workers can help in urging the public to see it when it is shown in their localities.

More complete information on the film appeared on page 319 of the March issue of the JOURNAL.

RESOLUTION ON THE DEATH OF JOHN P.
RUSSELL, M.D.

THE California State Board of Public Health at its meeting in Sacramento on March 20 voted a resolution of regret at the sudden death of John P. Russell, M.D., Chief of the Industrial Hygiene Services of the California State Department of Health since 1937. The resolution points out that his services represented an outstanding and a brilliant effort in the development of industrial hygiene, both in peace times and, more recently, while the nation has been at war.

Dr. Russell died suddenly in Berkeley on March 17. Bertram P. Brown, M.D., the California Director of Public Health said, "In Dr. Russell there was that rare combination of successful administrator and sound research scientist. . . . The state was exceedingly fortunate in having Dr. Russell's assistance during the formative years of the industrial hygiene program."

PERSONALS

Central States

FRED L. ADAIR, M.D.,* Mary Campau Ryerson, Professor of Obstetrics and Gynecology, and Chairman of the Department, University of Chicago, The School of Medicine, Chicago, Ill., has been appointed Chief of the Division of Maternal and Child Hy-

giene of the Illinois State Department of Health, Springfield.

CHARLES W. ATKINSON, of Boswell, Ind., has been reappointed as Health Officer of Benton County.

WILLIAM H. CAREY, JR., has been appointed as Regional Sanitary Engineer for the 6th and 7th Civilian Defense Regions with headquarters in Chicago, it is announced by the Office of Civilian Defense. Mr. Carey has been a public health engineer with the U. S. Public Health Service and Assistant Engineer with the Michigan State Department of Health.

ELTON R. CLARKE, M.D., of Kokomo, Ind., has been named Health Officer of Howard County.

JAMES H. CROWDER, M.D., II, of Sullivan, Ind., has been named Health Officer of Sullivan County.

ORVILLE A. DELONG, M.D., of Elizabethtown, Ind., has been reappointed as Health Officer of Bartholomew County.

CHARLES T. DOLEZAL, M.D., Assistant Clinical Professor of Medicine, Western Reserve University School of Medicine, Cleveland, Ohio, has been appointed Welfare Director of Cleveland.

GEORGE R. DOUGLAS, M.D., of Valparaiso, Ind., has been named Health Officer of Porter County.

THEODORE DOZOIS, PH.D., Bacteriologist and Serologist for the North Dakota State Department of Health laboratory at Bismarck, has resigned to accept a teaching and research position at Western Reserve University, Institute of Pathology, Cleveland, Ohio.

CHARLES L. FAHNESTOCK, M.D., of Lincoln, Neb., was appointed Supervisor of the State WPA Public Health Projects on February 1.

ROBERT M. FERGUSON, M.D., Indianapolis, has been named Director of Health District No. 4, with headquarters in Rising Sun. He succeeds DR. GEORGE M. BROTHER,[†] who is now Chief of the Bureau of the local health administration, Indianapolis. District No. 4 includes the counties of Dearborn, Ripley, Jefferson, Switzerland, and Ohio.

WESLEY GILBERTSON, B.S., M.S.,[†] and HARRY G. HANSON, B.S., M.S., both of the Sanitary Engineering Division of the North Dakota State Department of Health, have been employed by the U. S. Public Health Service and are doing malaria control work at Atlanta, Ga.

JOHN S. GILKISON, M.D., of Shoals, Ind., has been named Health Officer of Martin County.

FRED W. GRAYSTON, of Huntington, Ind., has been reappointed as Health Officer of Huntington County.

JAMES R. HAMILTON, M.D., of Mitchell, Ind., has been appointed City Health Officer, to succeed the late JAMES D. BYRNS, M.D.

OLAF HAROLDSON, M.D., who has been doing private practice in North Dakota, has been appointed Health Officer for a city-county health unit at Minot, N. D. Dr. Haroldson and E. L. SEDERLIN, M.D.,[†] City Health Officer of Fargo, N. D., are doing advanced field work in the State of Missouri.

OSCAR S. HELLER, of Greenfield, Ind., has been reappointed as Health Officer of Hancock County.

JAMES E. KEELING, M.D., of Waldron, Ind., has been named Health Officer of Shelby County.

OLIVE E. LEE, R.N.,[†] Assistant State Supervisor of Public Health Nursing, North Dakota State Department of Health, has recently been appointed Consultant in Nursing for the American Red Cross and will be stationed in the midwestern district.

* Fellow A.P.H.A.

† Member A.P.H.A.

Eastern States

CAPTAIN CHARLES C. AGAR, Senior Sanitary Engineer, in charge of sewage disposal plants, State Department of Health, Albany, N. Y., was called for active duty and reported to the Commanding Officer at Fort Dix on April 1.

ROBERT S. BREED, PH.D.,* Chief and Research Bacteriologist, New York State Agricultural Experiment Station, Geneva, N. Y., has for some months been on leave in Latin America, consulting on problems of milk production under the auspices of the Inter-American Committee for the Dairy Industry.

WILLIAM A. BRUMFIELD, M.D.,* Director of the Division of Syphilis Control of the New York State Department of Health, Albany, has been called for duty with the Army Medical Corps, effective April 13. In his absence JAMES H. LADE, M.D.,† will act as Director of the Division of Syphilis Control.

ALTON S. FELL, M.D., of Trenton, N. J., retired recently as Health Officer of Trenton, after a service of 43 years.

S. S. GOLDWATER, M.D.,* formerly Commissioner of Hospitals and now President of the Associated Hospital Service, New York, N. Y., was cited for "his invaluable contributions to the art of hospital planning and his outstanding services to the City of New York as Commissioner of Hospitals" at the 85th anniversary dinner of the New York Chapter of the American Institute of Architects on March 10.

JOHN HALL,* Field Supervisor with the Venereal Disease Division of the New Jersey State Department of Health, Trenton, N. J., has been appointed by the U. S. Public Health Service as a public health engineer on the

staff of District No. 3, with headquarters in San Francisco, Calif. This district includes California, Oregon, Washington, and Nevada. Mr. Hall is Executive Secretary of the New Jersey Health and Sanitary Association.

A. J. LANZA, M.D.,* Assistant Medical Director of the Metropolitan Life Insurance Company, New York, N. Y., has been appointed Lieutenant Colonel in the Medical Corps of the Army and assigned to the Division of Industrial Health in the office of the Surgeon General, Washington, D. C. Colonel Lanza will be Chief of the Occupational and Military Hygiene Sub-Divisions, Preventive Medicine Division, and will have responsibility for initiating, coördinating, and supervising all activities of the Medical Department in connection with the industrial hygiene program of the Army.

A. HELEN MARTIKAINEN, M.P.H.,† Health Education Secretary of the Hartford Tuberculosis and Public Health Society, Hartford, Conn., has resigned, effective June 1, to become Assistant Health Education Consultant under the U. S. Public Health Service.

DR. EDWIN P. MAYNARD, JR., has been appointed Chairman of the New York Heart Association, the Heart Committee of the New York Tuberculosis and Health Association.

LIEUTENANT DANIEL P. McMAHON,* District State Health Officer with headquarters in Amsterdam, N. Y., was called for active duty with the U. S. Navy and reported at the Norfolk Naval Hospital, Portsmouth, Va., on February 26. DR. C. A. SARGENT, who has been on sick leave for several months, replaces Lieutenant McMahon at Amsterdam.

CLAUDE C. PIERCE, M.D., who retired March 1 as a Medical Director of the U. S. Public Health Service after 42

* Fellow A.P.H.A.

† Member A.P.H.A.

years of service, latterly in charge of District 1, New York, N. Y., has been appointed Medical Director of the Planned Parenthood Federation of America, Inc., New York, N. Y. This organization was formerly the Birth Control Federation of America, Inc.

M. J. PLISHNER, M.P.H.,† of the staff of the Brooklyn Tuberculosis and Health Association, Brooklyn, N. Y., has been called to the Army as 1st Lieutenant in the Sanitary Corps and is now stationed at Ft. Story, Va.

JOHN W. TRASK, M.D., has been appointed Acting Health Commissioner of Pittsfield, Mass. Dr. Trask retired recently after a career in the U. S. Public Health Service, serving at one time as Assistant Surgeon General in charge of the Division of Sanitary Reports and Statistics and more recently as Medical Officer in charge of various Public Health Service hospitals.

Southern States

ERNEST A. COOK, M.D.,† of Wedowee, Ala., has been appointed Health Officer for Cleburne County, succeeding CORINNE S. EDDY, M.D., M.S.P. H.,† of Centerville, resigned.

HATCH W. CUMMINGS, M.D., is the new Health Officer of Hearne, Tex.

COLONEL GEORGE C. DUNHAM, M.D., DR.P.H.,* Washington, D. C., M. C., U. S. Army, on his appointment as Director of the Division of Health and Sanitation in the Office of Inter-American Affairs, U. S. Department of State, was appointed Brigadier General. The United States Congress confirmed the appointment on March 2 before General Dunham left for South America.

CHARLES JACK FISHER, M.D., of Montgomery, Ala., has been appointed

Health Officer of Tuscaloosa County, effective April 1. He succeeds ARTHUR A. KIRK, M.D., who resigned after many years of service. Dr. Fisher, who is now in charge of the venereal disease program of the State Department of Health, formerly served as Health Officer of Butler County.

HUGH R. LEAVELL, M.D., DR.P.H.,* Health Officer of Louisville, Ky., has been appointed Director of Health for a newly consolidated health unit made up of the Louisville City and Jackson County Health Departments. The consolidation has been accomplished through an act of the Kentucky State Legislature and includes not only the health departments but the medical care programs, the City Hospital and the tuberculosis sanatorium.

THOMAS M. LITTLEPAGE, M.D., of Mount Sterling, Ala., has been appointed Health Officer of Choctaw County.

WILBUR D. LUNDQUIST, M.D.,† of Waynesboro, Ga., Health Commissioner of Burke County, will during the present year devote half of his time to Jenkins County, which has been without a Health Officer since ISBIN S. GIDDENS, M.D.,† of Millen, resigned to enter the Army.

HAROLD MARKS, M.D., Passed Assistant Surgeon (R), U. S. Public Health Service, has been assigned to the Medical Division of the Office of Civilian Defense. Dr. Marks recently has been at the National Institute of Health, Bethesda, Md., and was engaged in making medical surveys of medical care in defense communities.

ANTHONY RALPH MARSICANO, M.D., formerly of Coolidge, Ga., has been named Health Commissioner of Coffee County.

WILLIAM B. PATTERSON, M.D.,* of Brownfield, Tex., is the new Director of the five county health unit serving Dawson, Hockley, Yoakum, Gaines,

* Fellow A.P.H.A.

† Member A.P.H.A.

and Terry Counties, with headquarters in Brownfield.

DUDLEY A. REEKIE, M.D., who has been Chief Medical Officer of the Tennessee Valley Authority, Chattanooga, has been appointed Regional Medical Officer of the First Civilian Defense Region, with headquarters in Boston. Dr. Reekie was formerly associated with the Kentucky State Board of Health as Field Director of County Health work.

LEONARD A. SCHEELE, M.D.,† Passed Assistant Surgeon, U. S. Public Health Service, has been assigned to the Medical Division of the Office of Civilian Defense, to serve on its Washington staff.

PAUL L. WERMER, M.D.,† of Gilmer, Tex., has been named Health Officer of Upshur County.

STEPHEN W. WILSON, M.D., of Gilmer, Tex., was recently chosen Director of the new City Health Unit at Atlanta, Tex.

Western States

D. M. BISSELL, M.D.,† has been appointed Health Officer of the City of San Jose, Calif., succeeding Dr. H. C. BROWN, who died. Dr. Bissell was formerly Health Officer of Monterey County.

Hawaii

MARY H. LEMON,* Registrar General of Vital Statistics, Board of Health, Honolulu, is retiring from Public Service in Hawaii.

Canada

DR. KINGSLEY KAY,† who has been Acting Chief of the Division of Industrial Hygiene, Department of Pensions and National Health, Ottawa, Ont., is now on active service with the Royal Canadian Navy, Technical Branch.

Foreign

DR. ALBERTO RECIO,† has been appointed Director of Sanitation in the Ministry of Health and Welfare of Cuba, Havana.

JULES THEBAUD, D.D.S., of Port au Prince, Haiti, was appointed Director of the National Department of Hygiene and Public Health in Haiti on January 16. He has been director of the dental school in Port au Prince since 1928, and is the founder and President of the Société Dentaire d'Haiti.

DEATHS

M. LOUISE DIEZ, M.D.,* Director of the Division of Child Hygiene of the Massachusetts Department of Public Health for the last 13 years, died April 11, at the age of 63. Before her State appointment, Dr. Diez had held positions in Philadelphia hospitals and in Providence, R. I. Then she served as obstetrician in the Division of Maternity, Infancy and Child Hygiene, New York State Department of Health, and as Associate Director of the same Division.

ROBERT W. HEGNER, PH.D., Professor of Protozoölogy at the Johns Hopkins University School of Hygiene and Public Health, Baltimore, Md., died on March 11, at the age of 62.

JOHN P. RUSSELL, M.D., M.S.P.H.,* of Berkeley, Chief of the Industrial Hygiene Services of the California State Department of Public Health, died on March 17.

ROCK SLEYSER, M.D., psychiatrist of Milwaukee, Wis., died March 7. He was President of the American Medical Association in 1939.

MARTHA TRACY, M.D., DR.P.H.,† Assistant Director of the Philadelphia Department of Public Health, died March 22, at the age of 65. A graduate in 1904 of the Woman's Medical College in Philadelphia, Dr. Tracy received the Dr.P.H. in 1917 from

* Fellow A.P.H.A.

† Member A.P.H.A.

the University of Pennsylvania. In 1924 she became Professor of Preventive Medicine at the Woman's Medical College, and in 1931 Dean, in which position she served until she became Assistant Director of the

Department of Public Health in 1940.

JOHN A. VOGLESON, Civil Engineer, Philadelphia, Pa., died on January 16. Major Vogleson was a Charter Fellow from 1923 to 1933.

The Index Person—Relation to Incidence Rates in Family Studies*

ROSS L. GAULD, M.B., DR.P.H., LOWELL J. REED, PH.D.,
F.A.P.H.A., AND MARGARET MERRELL, Sc.D.†

*School of Hygiene and Public Health, The Johns Hopkins University,
Baltimore, Md.*

MUCH of the information available regarding the communicability of various diseases and the conditions related to exposure, susceptibility, and immunity is derived from observation of their spread or failure to spread in attacked families. Most studies of disease within family or household groups have been presented, however, in an incomplete form, so that the published data are unsatisfactory for comparative purposes and are difficult to interpret. The correction of these defects is not always a simple matter, for the use of family units as a basis for study introduces unexpected complications, and these complications are not the same for acute as for chronic diseases.

The systematic study of the acute communicable diseases, using the family or household as a unit, has been due

largely to the work of the late Charles V. Chapin¹ and his development of the so-called "secondary attack rate" to measure the risk of persons exposed to a disease in another member of the same household. The secondary attack rate can be compared with the incidence in the general population to show the increased risk resulting from familial exposure. In calculating secondary attack rates, the primary cases which introduce the disease into the attacked families are excluded from the tabulations because they do not belong to the same universe of study as do their household associates. The universe of study to which the primary cases belong is the general population, whereas the familial associates comprise a universe in themselves, since they represent all persons living in familial contact with the primary case.

The use of secondary attack rates cannot readily be carried over into studies of chronic disease to measure the risk within attacked families. For one thing, it is impossible in most instances to denominate the primary case

* Read at a Joint Session of the Vital Statistics and Epidemiology Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 16, 1941.

† From the Departments of Epidemiology and Biostatistics (Paper No. 219), School of Hygiene and Public Health, The Johns Hopkins University. Supported by a grant from the Commonwealth Fund.

who must be responsible for the introduction of the disease into the family. Attempts to use the "earliest known case" as the primary case, and calculate secondary attack rates on this basis, give a pseudo secondary attack rate which is too high to represent the risk within exposed families, for reasons which will be discussed later.

Another difference between the study of acute and chronic disease is that, in the chronic diseases, the period of peculiar risk within attacked families is not confined to a few weeks, as in the acute conditions, but instead extends over a period of years. Because it is difficult to keep a sufficiently large group of people under systematic observation for a long period of time, most studies of chronic disease within family groups have been of a *retrospective* nature, and rely upon such simple facts as may be expected to lie within the memory of the average householder.

These difficulties have so far defied all attempts to calculate secondary attack rates in chronic disease studies, but they do not prevent the calculation of incidence rates for these families, provided the analysis of the family experience is linked with the time of onset of the disease in the person responsible for the selection of the family, *i.e.*, the index person.* Such rates must of course accommodate for time by using some form of modified life table procedure and expressing the population at risk in person-years of experience.^{2, 3} These rates, while not secondary attack rates, are true incidence rates, and can be compared with the incidence in the general population. It is thus possible to measure the risk in these families and its relation to that in the population proper for the period subsequent to the

onset of the disease in the index person and, in certain cases, for the period prior to this onset. Such rates are meaningful, are readily interpreted, and are of distinct value in the study of chronic disease.

Although the late Dr. Wade Hampton Frost is largely responsible for the introduction of the use of these rates to measure the risk in attacked families, he had published no report on the subject at the time of his death. The purpose of this article is to repair this deficiency and to consider in broad terms the determination of incidence rates in family studies in relation to the bias introduced by the index person.

DEFINITION OF TERMS

The term "family" is used to refer to the group of individuals who dwell together as a household under one roof. That is to say, a family is composed of a group of people, usually of close kinship, who are living in intimate contact with each other and who share a common environment. It is, as a rule, a readily delineated group, and is a unit which can without great difficulty be kept under observation. The terms "family" and "household" are used synonymously throughout the discussion.

The "index person" is defined as that member of the family responsible for its inclusion in the study. Whenever the household is used as the unit of study, there must be an index person in each family, although this fact is not at first apparent. In most instances the families are selected for study because a specific event, such as attack with a disease, is known to have occurred in some one member of the household. This person is denominated the index person because, although not necessarily the first member of the family in whom the event has occurred, he is the first member of the family to come to the attention of the investigator. If the event is a reportable disease, the terms

* The term "index person" is used in preference to the term "index case" in common use because the word "case" carries certain implications not always fulfilled by the index person. The index person is sometimes referred to by geneticists as the "proband."

"index person" and "first case reported from the family" are synonymous. In other instances, where no attempt has been made to select families because of a specific occurrence to one of its members, and all families within an area are studied, it would appear that there would be no index person because no conscious selection of families is made. Even in such cases, if the study is a dynamic one, there is an implicit selection of families due to the person responsible for the maintenance of the family as a unit. Through this responsibility, this individual acts as the index person. This concept will be discussed in some detail later.

The term "population at risk" is used to describe the particular group of individuals (the universe) in which each is liable to the event in question. In calculating the usual annual mortality and morbidity rates, the population at risk is defined as the mean population under consideration during the year of observation. In family studies dealing with chronic disease, the population at risk is usually expressed in person-years* of observation, when an annual rate is desired.

The term "incidence rate" expressed for a specific unit of time refers to the rate derived from the application of the formula

$$\text{Incidence rate} = \frac{\text{Number of events in the population at risk in the specified time}}{\text{Mean population at risk of event during specified time}} \quad (1)$$

(X)

In this formula the event may be death, contraction of a disease, or any other defined occurrence. The rate may refer to the number of events in 1 week, 1 year, 10 years, etc., depending upon the time specified. In the study of chronic disease it is more usual to derive the incidence rate from the formula:

$$X = \frac{\text{Number of events in population at risk during observation}}{\text{Person-time units of risk during observation}} \quad (2)$$

This formula is the equivalent of formula (1), but its expression shows more clearly that allowance is made for variation in the length of observation for different individuals. A person-time unit of risk may be 1 person at risk for 1 year, 1 week, 1 month, etc., depending upon the time unit selected. In the following discussion of incidence rates, the time unit will be selected as a year, merely for the sake of concreteness, but the discussion applies equally well to rates based on any other specified unit.

ANALYSIS OF INCIDENCE RATES DERIVED FROM FAMILY STUDIES

In setting up for families incidence rates which are comparable to those for the general population, it is necessary to consider how the event for which the families were selected is related to the event for which the incidence rate is set up. A formula for calculating incidence rates including all members of the family may be expressed

$$X = \frac{\text{Number of events in members of the family during observation}}{\text{Person-years of risk in members of family during observation}} \quad (3)$$

Such a rate is comparable with that in the general population only if, for the event in question, all members belong to the same universe of study. The pertinent question, then, is how the index person, who brought the rest of the family into the study, came into the study himself. If his selection was related to the event under study, while that of the rest of the family was not, then all members of the family do not belong to the same universe of discussion. This point can be illustrated by considering the various relationships which can exist between the event which caused selection of the index person and the event which is being studied, and

* One person-year means 1 individual observed for 1 year, or its equivalent.

these will be discussed in four different classes.

I. *Families chosen because the event being studied has occurred in the index person—*

The great majority of family studies of disease are of this type. They are set up to study the further occurrence of a disease in households where it is already present, households being chosen in which at least one member is known to be suffering from the disease. The individual thus responsible for the inclusion of the family is the index person, and he may be one of a series of reported cases or of admissions to a hospital or clinic. The selection of the index person involves, therefore, his having the disease which is to be studied, and his coming to the attention of the investigator through clinic attendance or other case discovery mechanism. The index person is not selected because he is a member of the family; rather, the family is selected because of its association with the index person. The individuals in the family group, therefore, may be broken into two distinct classes, (a) the index persons, and (b) their familial associates, and we may consider these two classes as they relate to incidence rates.

(a) *Index persons*—Since in the present class of problem, all index persons *must* by definition have the event under consideration, they are 100 per cent attacked. If they are included in the calculation of incidence rates, they must all appear in the numerator of the rate. These persons do not come from the universe of the family group but, instead, from a broader and much less definite universe. For instance, where index persons are selected because of attendance at a clinic, the universe from which they are drawn may be defined as "all persons who, if they had developed the disease, would have come to that particular clinic." This is an

unmeasurable universe, since there is no method of knowing what individuals (who did not develop the disease) would have come to the clinic if they had been attacked. Where index persons are an entire group of legally reported cases of a disease, the universe is measurable, and may be taken to be the entire population of the area. In no case, however, can it be considered as being the family group.

(b) *Familial associates of index persons*—These individuals are selected because they share a common environment with the index persons. They comprise a complete universe in themselves and, in addition, are selected without prior knowledge of the occurrence of the disease among them.

With the family membership separated into these two classes, we may inquire into the justification of combining them into formula (3), which calls for dividing all the cases in both index persons and their associates by the combined person-years of risk in the two groups. Since the justification for setting up the combined rate depends upon the two groups coming from the same universe of discussion, we shall examine the two groups for this issue.

If we consider the contribution of the familial associates of the index persons (group b) to the whole experience, we may set up the ratio

$$\frac{\text{Number of events in associates during observation}}{\text{Person-years of risk of associates during observation}} \quad (4)$$

This is a true incidence rate because the denominator forms a complete universe and the numerator contains all the events which occurred within it. The group was not selected for the presence of the disease, but merely for the association with the index person, and the incidence rate may be compared with that of the general population to see the effect of this association.

On the other hand, the contribution

of the index persons (group a) to the total family experience is of different character. Setting up a similar ratio for their contribution, we have as stated earlier all the index persons in the numerator, since they were selected because they were known cases. The ratio is then

$$\frac{\text{Number of index persons}}{\text{Person-years of risk of index persons during observation}} \quad (5)$$

The denominator of this ratio needs some clarification. Since the index person had already been attacked when selected for study, the observation period is a retrospective one, and dates from his entrance into the family unit. Formula (5) therefore divides the number of index persons by their total years of experience from entrance into the family until attack. This expression is then merely the proportion of these known attacks which occurred per year. It is obvious that the denominator does not include the universe at risk of becoming an index person, and hence the ratio is not an incidence rate at all.

We note, therefore, that where families are chosen because the event being studied has occurred in the index person, the members of these families must be considered as having come from two distinct universes with respect to this event. The type of data obtainable for index persons is not comparable to that for their associates, and hence the two cannot with justification be lumped together. If these data, which yield "proportion of known attacks occurring per year," and "proportion of persons at risk attacked per year" (*i.e.*, incidence rate) be combined, the resulting conglomeration cannot possibly be interpreted.

We have stated that from the experience of the familial associates of the index person we can set up a true incidence rate, and it is of interest to know how this rate in chronic disease com-

pares with the usual secondary attack rate in acute disease. It is apparent that the two rates are very similar, since in both instances they are calculated from the experience of familial associates of known cases. However, it must be remembered that the index person may not be the same as the primary case, since he is not necessarily the first person attacked.

It might appear possible to secure secondary attack rates in chronic disease studies by substituting "earliest known case" for "primary case" and dealing with the experience of the familial associates of this case rather than with those of the index person. Where, however, families are selected because of the occurrence of disease in the index person, they usually have a larger proportion of multiple cases than would be found in all families in which the disease occurs. This is due to the fact that the probability of there being an index person in the family, that is, the probability of there being a discovered case, increases as the number of cases in the family increases. Hence, there is a tendency to select for study, families having two or more cases and to fail to include a sufficient number of families with only one case. The families in the study may not be representative, therefore, with respect to the occurrence of cases subsequent to the earliest known case, and any pseudo secondary attack rate calculated tends to be too high to serve as a measure of the risk. Since the proportion of primary cases which become index cases is usually unknown, and in all probability varies in different studies, no correction is possible and hence no reliable measure of risk can be obtained on this basis.

Reliable measures of the occurrence of chronic diseases can, however, be obtained by comparing the incidence of a disease among the family associates of index persons after the onset of the index case, with that in the general

population. In studies where there is no bias tending to make the index person the first case in the family, rates may be set up to compare the experience of the family associates prior to and subsequent to onset of the index case. In making such analyses, the index person is not a part of the universe of study, and should be excluded from the tabulations.

II. *Families chosen because the event being studied is related to an event which has occurred in the index person—*

This situation involves the same logical issue as that discussed above. The difference in the two classes of problem is one of degree only, for in this case the event being studied has not necessarily occurred in the index person, but it is related to the event for which he is selected. Thus, the members of the family belong to two distinct universes, since the risk of the event for the index person, although not certain as before, is different from that for his familial associates. This case is illustrated by studies of the mortality from tuberculosis in families in which the index person is known to be suffering from the disease. Here the event being studied is death, and the event which has occurred in the index person is the development of tuberculosis. In analyzing formula (3) for the inclusion of all members of the family, we find that the contribution of the index person is

$$\frac{\text{Number of events in index person during observation}}{\text{Person-years of risk in index persons during observation}} \quad (6)$$

In this instance the index person has had an event, the onset of the disease, which makes him more liable to the event, death, which is being studied. We thus obtain an incidence rate of mortality among these persons which is the mortality rate of persons known to have the disease. This rate must neces-

sarily be much higher than any rate calculated for the household associates of these index persons from

$$\frac{\text{Number of events in associates during observation}}{\text{Person-years of risk of associates during observation}} \quad (7)$$

because the probability of mortality is greater among those who are known to have the disease than among their associates for whom the occurrence of the disease is not mandatory. While in this case we have two incidence rates, they are of a different order, and hence should not be combined. If the purpose is to obtain a measure of the comparative risk of death in these families and the general population, the index persons must be excluded from the tabulations, and the analysis be confined to the experience of their household associates.

III. *Families chosen for an event in the index person which is not related to the event being studied—*

If the selection of the index person is by some mechanism having no relationship to the event under study, then the index person and his family share a common risk to the event, and may be considered as belonging to the same universe. This case is illustrated by such studies as those of the common cold in the families of army officers. Here the index person enters the study because he is an army officer, which bears no appreciable relationship to risk of the event under consideration, namely, the common cold. In setting up the rate for common cold, formula (3) may be used and it is unnecessary to exclude the index person or to consider his experience separately.

IV. *All families in an area included in the study—*

When all families in an area are included, it might appear that there was no selection involved and that we were dealing with the case just considered

under (III). However, in dynamic studies which are retrospective, where the family is the unit, there is a bias present which is related to the index person. This is most apparent in studies on mortality, and will therefore be discussed for this case.

Suppose a canvass were made of all families resident in a city as of January 1, and reasonably accurate answers were obtained to the following questions from each family present:

1. How many people live in the household now?
2. How many people lived in this household a year ago?
3. How many people died in this household during the year?

It might be expected that the mortality rate for this city during the year could be obtained from the formula

$$\frac{\text{Number of deaths in families during year}}{\text{Mean population of families during year}} \quad (8)$$

but this rate would be too low to represent the mortality rate in the city.

The reason for this is that, in spite of the fact that all families present in the city at the end of the year are included, these are not all of the families present *during* the year. Only those families which are existent on the day of survey are included, and no data have been obtained on the families which ceased to exist as such during the year. To appreciate the bearing of this on the mortality rate, we should consider the reasons for families passing out of existence.

It is, of course, apparent that a family will cease to exist if all of its members die. This is not a rare occurrence in one-member families, it is less frequent in two-member families, and the probability of its occurrence decreases as the size of the family increases. It is certain, however, that if no member of the family remains alive, the family is non-existent, and when a survey is made, no record will be obtained of such families,

although deaths in them will have contributed to the total mortality of the area.

But it is not necessary for all members of a family to die for the unit to become nonexistent. For example, if a family consists of a widow and 4 young children, the death of one of the children would not necessarily break up the family unit, but if the mother dies, there may be no other individual capable of maintaining the family as such. The result is that the family is dispersed, the children enter new households, and any data obtained upon them in the survey will not include their experience in the "dead" family. In general, we can say that families break up because of the removal from the group (by death or for other cause) of one member whose continuance in the household is essential for its existence as a unit.

If families break up for this reason, it follows that if they are to continue to function as units, each must contain at least one individual capable of holding the group together—one member who serves as a "binding post" to maintain the unit. This means that in each existent family there is one individual (almost invariably an adult) who *must* be living. This individual is designated the index person because his survival to the time of investigation is responsible for the inclusion of the family in the study.

With this in mind, let us now consider the composition of the population on which we obtained data in the canvass covering all families of the city, and the contribution of its members to the mortality rate of formula (8). The contribution of the index persons may be expressed as

$$\frac{0}{\text{Mean population of index persons during year}} \quad (9)$$

since the index person, by definition, must be living. The contribution of the

familial associates of the index person is

$$\frac{\text{Number of deaths among familial associates during year}}{\text{Mean population of familial associates during year}} \quad (10)$$

which is a true rate.

This analysis indicates that the index person is not at risk of the event which is being studied. The fact that he can contribute only to the denominator of ratio (8) and not to the numerator is directly responsible for the deficiency of the rate calculated with all members included. To obtain a true mortality rate for the area, the index person must be excluded.

It thus follows that in each family, the member designated as the index person must be determined. In family studies where the households are selected *because* of the occurrence of a specific event in the index person, there is no question of his identity. When all existent families are included, however, the denomination of the index person is not so certain. By our definition, the index person is that individual responsible for the inclusion of the family in the study, and if all existent families are included it is, therefore, the person responsible for the maintenance of the family as a unit. Such a person must almost certainly be an adult and must be capable of holding the household together. In families in which there are two or more such individuals, the preferred method of designating the index person is by some random selection from among the qualified individuals. This method is preferred to that of making the terms "head of the household" and "index person" synonymous, which would tend to exclude an undue proportion of male members from the population at risk.

SUMMARY

In investigations where the family is the unit of study, the index person is

the member responsible for bringing the rest of the family into the study. If incidence rates for some event are to be set up on the family experience, and compared with those in the general population, it is critical to determine whether the event causing selection of the index person is in any way related to the event under study. If there is any relationship whatsoever between the selection of the index person and the event for which the rate is set up, then the index person belongs to a different universe of discussion from that of his familial associates, and should be excluded from the calculations. This relationship may be positive, that is, the index person may certainly have, or be at increased risk of having, the event being studied. This case is illustrated by studies of morbidity or mortality of tuberculosis where the index person is a known case. On the other hand, the association may be negative where the index person has no risk, or a decreased risk, of the event in question. This is illustrated by the retrospective study of mortality or morbidity in family groups where the survival of the index person is essential to the inclusion of the family in the study. In all such cases, the experience of the index person and that of his family associates cannot be combined to produce meaningful rates.

In the rather rare family studies where the choosing of the index person is entirely unrelated to the event under study, and where only the family experience subsequent to the time of selection of the family is considered, the index person and his family associates may be considered as belonging to the same universe of discussion, and incidence rates for their combined experience may be set up.

Family Records in the Health Department*

GEORGE H. RAMSEY, M.D., F.A.P.H.A., AND
MARJORIE T. BELLOWS, F.A.P.H.A.

*Commissioner, and Statistician, Westchester County
Department of Health, White Plains, N. Y.*

THE health officer realizes that in the course of his work many services rendered on behalf of an individual affect other members of the household, and sometimes deals with the family as a group when he encounters a specific problem in a home. But much of his thinking is in terms of cases reported and individuals served, and the word "family" seldom appears in health department annual and special reports; or for that matter in textbooks on public health organization. Development of methods for using the family as an administrative unit by nursing and social agencies, and growing interest in studies such as those presented here, make it desirable to explore the situation as to family records now existing in health departments. One may then speculate as to what extent keeping account of services on a family basis might contribute to more efficient administration and provide material for research.

Family information is commonly found in three types of health department records, namely, clinical history sheets, nursing folders, and communicable disease investigation forms. The medical term "family history" was obviously borrowed from hospital and

dispensary practice many years ago and the purpose was to assist the clinician. A space on record forms was sometimes labelled "family history" without amplification, and sometimes the father, mother, and other relatives were mentioned.

Among forms of this type were cards or sheets used in tuberculosis clinics. Here it was the clinician who wanted family data to aid in diagnosis, and the records were not primarily designed for use in contact investigations and other control measures. Some health departments soon found it necessary to keep a roster of members of tuberculous families, but among a group of large cities from which record forms were collected as recently as 1929, there were still two without provision for a household roster on tuberculosis forms. Moreover the term "family history" was repeated on several blanks in all cities.

Public health nurses in official agencies are under the impression that they began to list members of households when home visiting became a part of tuberculosis control. Visiting nurse organizations kept family records much earlier, and were influenced by closely related social and welfare groups. When organized in the 70's, "family societies" apparently copied many of their record keeping systems from charitable organizations in England. By twenty or twenty-five years ago, "so-

* Read at a Joint Session of the Vital Statistics and Epidemiology Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 16, 1941.

cial data" or "history" sheets were common to social work, and to official and voluntary nursing records. These for the most part, however, were for administering current situations, rather than for keeping permanent, continuous records of what happened to families. An interesting proposal for voluntary continuous registration of important events in family life was made by Taylor in 1912.

Although a fairly diligent effort has been made to do so, it has been impossible to determine by whom the nursing family folder was originally devised or by what nursing service it was first used. Writing in 1920, Olmsted described a family folder for the rural nurse working alone or in a small unit. Discussing the advantages of such a system, she declared that it saves clerical labor, since information regarding the family is not repeated on various forms. She also said that it helps to impress upon the nurse the effect of wages and environment, and aids in coöperation with other agencies; it assists in communicable disease control, and in collecting statistics.

The necessity for having as complete a picture of the family as possible, and for assembling all facts in one place, developed in larger communities with the change from specialized to generalized nursing. Family folders became a part of the record system of many official and voluntary nursing agencies by the middle of the 1920's, and their use has been continued and extended since. Thus, in the nursing field, the family is an established administrative unit, but even here the records may not be suitable for analysis to evaluate activities and services.

According to Frost (1938), Chapin deserves the credit for being the first in this country to list routinely members of households in which communicable disease occurred, and numbers of exposed persons became ill. Dr. Chapin's

own statements quoted by Frost indicate that he thought of using the information he collected for study as distinguished from administrative purposes. He speaks of family records for acute communicable diseases in relation to "scientific investigation" and of "collecting facts which perhaps are not of much value in themselves but may be when the number of cases can be increased." The results of his enumerations of exposed persons and cases among them must have been in his mind when he wrote on fumigation and other subjects, but they are rarely mentioned. And one of his close associates is of the opinion that he regarded his acute communicable disease data as of particular value for special studies.

His example of using local facilities for collecting information has not been followed in many health departments, either with respect to acute diseases or to tuberculosis and other chronic diseases more difficult to handle administratively and statistically. Some years ago it was planned to study mortality in upstate New York from streptococcus infections not diagnosed as scarlet fever but occurring in scarlet fever families. This was to be done by collecting case cards from all over the area and by comparing names of persons on such cards with registered deaths. The enterprise failed because the family roster on most cards was incomplete. Names written down were ordinarily those of children affected by quarantine and school exclusion regulations. Acute disease records such as this collection from a hundred or more local jurisdictions in the 1930's could not have been used for obtaining secondary attack rates, easily calculated from Dr. Chapin's observations long before the turn of the century.

It is apparent from the foregoing that family records have been developed independently by divisions, bureaus, or other units for a variety of reasons, and

that they are incomplete and scattered through health department services. The system devised in Westchester County to consolidate records and to bring the sum of family needs and services into prominence has been previously described in detail (Bellows and Ramsey, 1939).

This system provides for a steady flow of information between the central office and the field. There is a single folder for each family in which all medical and nursing records are bound together. The same folder contains child hygiene, tuberculosis, syphilis and orthopedic clinic records, as well as records of nurses' home visits. After each clinic the folder goes to the central office, where pertinent data are entered on case registers and in the department's master index. At the same time information revealed by the index which came directly to the central office is placed in the folder for the benefit of the field workers. The folder contains a summary sheet on which all services rendered to the family appear except those for minor communicable diseases such as measles and chicken pox. Each new family is cleared through the County Council of Social Agencies, and welfare and other agencies which have been in contact with the family are listed on the summary sheet.

A 4 years' trial has proved the advantages of the new record system. Clinicians find it helpful to have all the medical records of the family at hand when they are examining or advising their patients. Information obtained by physicians in clinics and nurses in the field is pooled, and the folder itself tends to encourage consultation between members of different divisions of the health department in deciding the best interests of the patient. The statistical division, using the same original records as the physician and nurse for its clinic and other reports, adds pertinent facts to them, such as information from case

and laboratory reports and birth and death certificates. The statistical division may find data in the folder of value to itself, such as facts that help in improving the accuracy of death certification, or tuberculosis and syphilis contact registers. Since the coördinated record system was introduced, the proportion of families carried on two or more clinic services has nearly doubled, the increase being from 356 to 708 families.

By using the folders and master index it is possible to obtain many facts of administrative interest. For example, it was found with little effort that among the 6,437 families enrolled on clinic services, 186 are households in which there are or have been cases of both syphilis and tuberculosis. Cancer has been reportable in New York State for only 18 months, but there are known to be 68 health department clinic families with cancer and tuberculosis cases, 24 in which there were both syphilis and cancer, and 8 families with cases of all three chronic diseases.

Additions are being made constantly to the pooled family records, and they should prove a body of information valuable for a wide variety of special studies. A year ago a study was undertaken of tuberculosis among familial associates of tuberculosis cases as compared with the same disease among familial associates of cases of syphilis. The tuberculosis rate among associates of that disease (1 per 100 person-years) was similar to that in other studies, and there was no evidence that tuberculosis was more prevalent among associates of syphilis cases than in the general population.

These findings appear to afford a more or less satisfactory test of the adequacy of the original records. Actually, it was necessary to correct and add to them before analysis could be undertaken. The most common fault was incompleteness of the family roster.

Members of the household who had left or died were often omitted, and sometimes an over zealous nurse listed transient visitors as members of the family. This experience led to a course of instruction for nurses on the content of a family roster, the reasons for filling out a roster completely in relation to their own work, and so that the record might serve research purposes.

The majority of family studies in recent years have been conducted under unusual circumstances with record forms quite different from those in routine use, and often with personnel outside of the regular health department staff. There is no question as to the value to the health officer of keeping his clinic and field records on a family basis. It also seems entirely feasible to maintain health department records of such a character and quality that they will be

suitable for studies in which life table methods and other statistical procedures are employed. And it should be possible to assemble data routinely with much less effort and expense than by special surveys. In other words, it appears that health officers themselves may well take cognizance of newer methods of statistical investigation and, even though unfamiliar with the pitfalls and technics of family studies, should give thought to the consolidation of record systems.

Nutrition Foundation Announces Policy for Grants

THE Nutrition Foundation, New York, N. Y., has announced that grants will be made to established institutions in the United States and Canada, the first series becoming effective July 1, 1942.

Problems of critical importance in the war emergency will be given primary consideration. Grants will also be made in the support of projects that

have a direct bearing upon public health.

Special concerns of the Foundation include dental caries, and nutritional requirements of infants, growing children, and the old age group. The Foundation's long-time program will place emphasis upon fundamental research to advance the frontiers of science.

Illness in the Chronic Disease Family^{*†}

JEAN DOWNES

Milbank Memorial Fund, New York, N. Y.

A STUDY of illness in a relatively small population composed of family units offers an unusual opportunity for observation of morbidity in particular groups of families. This report presents the illness experienced during a 12 month period by the members of 381 families selected because of a case of chronic disease from a total sample composed of 1,757 families living in the Eastern Health District of Baltimore.

In a previous report dealing with chronic disease among middle and old-age persons during the first year of the morbidity study in the Eastern Health District of Baltimore, it was shown that those with serious chronic disease carry the main burden of illness in the population after age 40 is reached. Ambulatory cases formed only 18 per cent of the total population. They not only had a higher frequency of attacks of illness but also suffered an excessive amount of disability in comparison with disability from illness in the remainder of the middle and old-age population. When families with chronic disease cases of all ages were considered, 25 per cent of the total families observed for a 12 month period had one or more members who reported the presence of chronic disease. This means that a considerable burden of

illness falls upon a relatively small proportion of the total families.¹

The study reported upon previously considered the illness experience of the chronic patients compared with illness in the rest of the population. Since the burden of illness of the chronic patient falls heavily upon his or her family unit, it is of interest to present the complete picture of illness in the chronic disease family by a consideration of the sickness record of the other members of the family, namely, those who have not reported the presence of chronic disease. The rate of illness for the chronic disease family may be compared with that of the remaining population.

When the special study was initiated, the Eastern Health District of Baltimore consisted of two city wards containing 11,896 white families or households, including 43,377 persons, and 3,413 colored households, including 13,784 persons.[‡] As far as the white population is concerned, the district is considered fairly representative of the localities in the city in which the wage earning population lives; that is, it contains some families in relatively poor economic circumstances, wage earning families in moderate circumstances, relatively few families in the professional class, and no families that can be classed as wealthy. Consequently, the

† From the Division of Public Health Methods of the National Institute of Health and the Milbank Memorial Fund.

‡ A few months after the special study of illness was started, the Eastern Health District was enlarged so that it now includes a population of approximately 100,000. Any reference to the Eastern Health District in this paper, however, is to the former district composed of Wards 6 and 7.

district cannot be considered as strictly representative of Baltimore as a whole, but it is probably representative of the population which forms the majority in the city.

There are three hospitals within the Eastern Health District and two adjacent to it. Each of these hospitals has an outpatient department. Approximately 150 private physicians practise regularly within the district. However, during the first and second years' study, from 300 to 400 different private physicians served the observed population.

DATA AND METHOD OF STUDY

The method of sampling in this particular study has been described in detail in a previous report.² It is sufficient here to say that the white families living in thirty-five city blocks formed the sample population. The plan of the study was to follow families that live in a group of houses in certain blocks rather than to follow a selected group of families. No attempt was made to continue visiting families that moved out of these houses during the period of the study, but the new fam-

ilies that moved into the houses vacated in the sample blocks were included in the study. Monthly visiting was employed in this study in order to secure a high degree of accuracy in the reporting of illness. The record of illness started with the first visit to the family; no attempt was made to secure a report of illnesses which had occurred during a period preceding the first visit, except illness existing on the day of the visit.

In the studies of illness conducted by periodic canvasses of families, "illness" may be considered to include any affection or disturbance of health which persists for a considerable part of one or more days. In this study, as in other family surveys, no specific definition of illness was formulated. The records of "illness" are of sicknesses reported by the household informant (usually the housewife), either as experienced by herself or as she observed them in her family.* Physical

* The causes of illness as reported by the family informants were submitted to the attending physician for confirmation or correction. The cause of illness for clinic attendance and hospital admissions were checked against the records of the clinic or hospital where the service was given.

defects or deformities, even though disabling, were excluded from this analysis. Illnesses present in the family at the time of the first visit were recorded, but in this analysis are not considered as illnesses occurring within the period of the study.

Representativeness of the Sample Population—The data for this analysis are based upon the experience of all families observed two months or longer during the second year of the morbidity study, that is, the year ending June, 1940. There were 1,757 such families, including both those which moved out or into the study area during the year. In the previous year there was a total of 1,796 families in the morbidity study which were observed two months or longer.

The sample population for the first two years of study was found to be representative of the universe from which it was drawn, the white population of the district, with respect to age constitution and size of household. The

age distribution of the population in the 1,757 families compared with the age distribution of the total white population of the Eastern Health District in 1939 is shown in Table 1. It is readily apparent that there are no important differences between the sample population and the total white population with respect to age content. The average size of white household in that year for the total district, 3.9 persons per household, was only slightly higher than in the sample population, where there were 3.8 persons per household.

Selection of Chronic Disease Families—The chronic disease families were selected for special analysis on the basis of the presence of an individual for whom any one of the following conditions or diagnoses was reported: mental disease or mental deficiency, neurasthenia or nervous breakdown, heart disease, hypertension or high blood pressure, arthritis, diabetes, varicose veins, gall-bladder disease, ulcer of the stomach or duodenum, chronic nephritis,

Cancer	1	0	1
Total	381	29	4	7	9	4	4	4	1	1	4	1	1	450

cancer, rheumatic fever and rheumatic heart disease, tuberculosis, and syphilis. Out of the total 1,757 families observed during the second year of study, 381 or 22 per cent reported one or more individuals with one of these diagnoses.*

It is recognized that such a group of diseases or conditions is homogeneous in only one respect, their tendency to chronicity. Tuberculosis and syphilis are known to be infectious diseases. Knowledge of the etiology and of the pathology of the remaining conditions listed is incomplete. Since this study is not concerned with the occurrence of secondary cases of chronic disease of like diagnoses in families, for purposes of observation of morbidity among other family members not affected, the experience of the 381 families has been combined.

Table 2 shows the families grouped according to the type of index case, the case which formed the basis of selection of the family. The total number of cases of chronic illness in each group of families is also shown. For some of the chronic diseases the number of families was very small. Families selected because of heart disease, hypertension, arthritis, mental disease and mental deficiency, neurasthenia, rheumatic fever, and diabetes were the most frequent. These families also had cases of chronic disease among members of the family other than the index case. In the total 381 families there were 29 individuals with a diagnosis similar to the index case in the family. There were 40 other individuals with chronic disease unlike the index case. In all, there were 450 cases in the 381 families.

The 381 family units afford two groups of population for study: the 450 chronic disease patients, 425 of which were ambulatory cases; and the

other members of the family with no reported chronic condition. The morbidity which occurred in these two population groups may be compared with the morbidity experience of the individuals in the 1,376 families in which no chronic cases of illness were reported.

The population groups with which this report is particularly concerned may be more clearly described as follows:

A. 1,376 families with no chronic cases—
Group 1

B. 381 families with one or more chronic cases—

Members of the family with no chronic disease—*Group 2*

Members of the family having chronic disease—*Group 3*

CERTAIN CHARACTERISTICS OF OBSERVED FAMILIES

Before a comparison of the morbidity experience of the three population groups is made, it is important to note the differences between the two classes of families with respect to characteristics such as migrant families (those which moved into or out of the study), social class, and age constitution of the population. The 1,376 families in which no chronic disease was reported had a higher proportion of migrant families, that is, families which moved into or out of the study area during the year; 27 per cent of these families moved, compared with 20 per cent of the 381 families. Families not classed as home owners are more apt to move; only 40 per cent of the 381 families lived in rented homes, and 53 per cent of the larger group of families were renters. The average size of the 1,376 households was 3.8 persons per household, compared with 4.2 persons per household in those selected on the basis of a case of chronic disease.

The distribution of each of the two groups of families according to the

* Chronic conditions such as chronic bronchitis, asthma, and hay fever have not been considered among the selected chronic diseases.

TABLE 3

Distribution of Two Groups of White Families in the Eastern Health District of Baltimore, According to Occupational Class of Head of Household, 1939-1940

Occupational Class of Head of Household	1,376 Families	381 Families
Professional	2.8	1.5
Business		
Proprietors	11.8	11.3
Clerks—Salesmen	13.2	16.2
Workers		
Skilled	28.2	28.0
Semi-skilled	31.8	31.1
Unskilled	12.1	11.9
All Classes	100.0	100.0

occupational class of the head of the household is shown in Table 3. Though the 1,376 families had a higher proportion of household heads in the professional class than in the 381 families, approximately 3 per cent in the former group compared with 1.5 per cent in the latter, the number of families in this class was so small that the difference between the two groups is unimportant. The point of greatest interest in the table is the striking similarity between the two groups of families with

respect to occupational class. From 24 to 27 per cent of the heads in each group of families were engaged in some form of business; approximately 60 per cent were classed as skilled or semi-skilled workers, and 12 per cent as unskilled workers.

From Table 4, which shows the distribution of three population groups by broad age groups and excluding children under 5 years of age, it is apparent that there are no important differences with respect to age between Groups 1 and 2, that is, individuals in the 1,376 families, and those in the 381 families who reported no chronic disease. However, when the chronic disease patients are added to the population of the 381 families, there is in this group a considerably greater proportion of older people, 60 years of age and over, than in the 1,376 families.

INCIDENCE OF ILLNESS AND MEDICAL CARE

In the following discussion of illness and medical care, confinements as a cause of illness are excluded. Table 5 shows the incidence of attacks of illness and the amount of medical care

TABLE 4

40-59	949	224	372
60 and Over	246	70	212

* Excluding individuals with chronic disease

for illness among persons reporting no chronic disease in the populations of each of the two groups of families, Groups 1 and 2, and excluding the patients with chronic disease. The cause of illness is shown for two broad classes, respiratory diseases and "all other" illness. Two classes of disabling illness are indicated by "bed illness," which include hospital illness, and "hospital illness" alone. These were illnesses which confined the individual to bed or caused admission to a hospital. Amount of medical care is expressed in terms of private physician visits (home and office) and clinic or dispensary visits.

Group 1 families. The rate of "bed illness" was 37 per cent higher in the Group 2 families and "hospital illness" was 21 per cent higher than was noted in the 1,376 families.

The incidence of medical care was also considerably higher, 34 per cent, for persons in the 381 families than for those in the 1,376 families. There were 1.5 physician visits per person per year for illness of "nonchronic" members of the 381 families compared with 1.2 visits per person for illness in the 1,376 families. The difference in the rates for clinic visits was even greater; the rate for persons in the small group of families was 48 per cent

TABLE 5

*Incidence of Attacks of Illness Among Persons with No Chronic Disease in Two Groups of Families: 381 Families (Index Case One with Chronic Disease) and All Other Families in the Eastern Health District of Baltimore, 1939-1940**

Classification of Illness and Medical Care	Group 1 3,708 Years of Life. All Other Families	Group 2 912 Years of Life. Persons in 381 Chronic Families, Excluding Chronic Cases Rate per 1,000 Population	Ratio of the Rate for Group 2 to Rate for Group 1

Deaths	5.9	6.6	1.12

* Includes only individuals 5 years of age or older

† Excluding confinements

The third column of Table 5 shows the ratio of the rate for the Group 2 population (381 families) to the rate for the Group 1 population, persons in the 1,376 families. Persons in the Group 2 population had an annual illness rate of 1,550 per 1,000 which was 23 per cent higher than the rate of 1,258 observed among persons in the

above the rate for those in the 1,376 families.

"Bed illness" and "hospital illness" may be judged as one indication of severity of illness. It is apparent that persons with no known chronic disease who were members of the 381 families suffered severe illness with greater frequency than did persons in

† Excluding confinements

the larger group of families. The consistency of the excess rate for all classes of illness in the Group 2 population suggests that these individuals constituted a more sickly group than did those of similar age in the 1,376 families.*

The incidence of attacks of illness of a nonchronic nature for individuals reporting the presence of a chronic disease or condition (the population of Group 3) is of interest at this point. The annual amount of illness for the 425 ambulatory patients 5 years of age or older, representing 389 years of life, is presented in Table 6. The crude rate of illness from all causes was 1,853 per 1,000 population, a considerably higher rate than was noted for either of the other population groups. When this rate is adjusted to the age distribution of the population reporting no chronic disease, it is reduced to 1,800 cases of illness per 1,000 population, a reduction of approximately 3 per cent. Age cannot be considered as an important factor influencing the level of the morbidity for this group of patients.

* Since the populations of Group 1 and Group 2 are quite homogeneous with respect to age, adjustment of the illness rates for age does not change their level.

The rate of disabling attacks of illness of a chronic nature is shown in the second column of Table 6. Such attacks greatly increase the total rate of bed and hospital illness. For example, the rate of hospital illness is increased from 67 to 108 per 1,000 population per year. On the whole, acute episodes of chronic disease represent severe attacks of illness.

The incidence of medical care which is related to the level of morbidity was also higher for the chronic disease patients than for the other two population groups. Physician visits for illnesses of a nonchronic nature were 2 per person compared with from 1 to 1.5 visits per person in the other two population groups. If medical care for acute attacks of illness of a chronic nature be included, it is apparent that ambulatory patients with chronic disease had considerably more care for illness than did persons in the other populations studied.

It is believed that the illnesses of a nonchronic nature for all three population groups are generally comparable. The excesses in the rates for the chronic disease families are summarized

Ratio of the Rate of Illness for
Populations of Groups 2 and 3
to the Rate for Group 1

FIGURE 1

in Figure 1 by presenting the ratio of the illness rates in their populations, Groups 2 and 3, to the rate for the remaining families observed during the second year of the morbidity study. It is clearly apparent that the rates for the three classes of illness, all illness (disabling and nondisabling), bed illness, and hospital illness were much higher in the chronic disease families than in the population of the 1,376 families. Among the chronic disease patients, Group 3, the ratios were 1.43, 1.58, and 1.43 for "all illness," "bed illness," and "hospital illness," respectively.

ATTENDED CASES OF ILLNESS

In Tables 5 and 6, medical care was expressed in relation to the total population. Medical care may be expressed also in relation to attended cases of illness. These data for illnesses of a nonchronic nature are shown in Figure 2 for each of the three population groups. The mean number of physician visits per attended case varied from 3.5 in Group 1 (the 1,376 families) to slightly more than 4 per case in the 281 chronic disease families. Groups 2

and 3. Clinic visits per clinic attended case were similar for the populations of Groups 1 and 2 with a mean number of visits of 4.7 and 4.9, respectively. Chronic disease patients (Group 3) had fewer visits, an average of 3 clinic visits per case.

It is of interest to show for each population group the proportion of illnesses of a nonchronic nature which had medical care. These data are shown according to classes of illness in Table 7. Although there are some variations among the three population groups in the proportion of attacks which received medical care in the various classes of illness, yet the three groups of population on the whole show a striking similarity. This fact may be clearly seen in Figure 3 where the data are presented graphically. Approximately the same proportion of the total illnesses in each of the three groups had medical care, namely, 33 to 34 per cent. The proportion of bed illness having medical care was also similar for the three groups, from 61 to 66 per cent of the total cases. If attended cases of illness in this particular population, where physicians' care and clinic care for illness is considered to be available to an unusual

Mean Number of Physician and Clinic
Visits Per Attended Cases in Three
Population Groups

FIGURE 2

Per Cent of Illness Having Medical Care in Three Population Groups

FIGURE 3

degree, may be interpreted as a reliable reflection of severity of illness, the surprising similarity in the three groups of population is of considerable interest. It would seem to indicate that regardless of the level of illness, either bed or all illness, a certain proportion will be severe enough to be thought by the individual to warrant medical care.

Acute episodes of illness of a chronic nature among ambulatory patients did not follow the same pattern as illnesses of a nonchronic nature. Sixty-nine per cent of all attacks of chronic illness and 82 per cent of the bed illnesses had medical care. This again emphasizes the severity of acute manifestations of chronic disease.

Another point of interest is a comparison of the three groups of population with respect to the proportion of

illnesses of a nonchronic nature that were bed illnesses and that were hospital illnesses. These data are presented in Figure 4. Again the three groups show

Per Cent of Total Illness That Was Bed Illness and Hospital Illness in Three Population Groups

 † Excluding confinements

very little variation. From 22 per cent of the total illnesses in Group 1, to 26 per cent in the Group 2 population caused the individual to be in bed one or more days. The proportion of the total illnesses which caused hospitaliza-

tion was identical for each of the three groups. It should be emphasized that confinements as a cause of illness have been excluded from all groups of population and, for chronic patients, attacks of illness considered to be due solely to

the chronic disease or condition have also been excluded from the data presented in Figure 4. It is interesting that the proportion of illness of a non-chronic nature which required a period in bed and which required hospitalization was very uniform in the different populations regardless of the level of illness. This can be explained on the basis that the relative excess over the rate for the Group 1 population was approximately the same for these classes of illness and for all illness.

This discussion so far has omitted a presentation of all medical care for the 425 ambulatory patients with chronic disease. In Table 6 medical care for the chronic patients was shown according to two categories—for illness of a non-chronic nature and for attacks of illness due to acute manifestations of the chronic disease itself. Medical care received for the chronic condition during the period when there were no acute episodes was not included. Table 8 presents the total medical care received during a 12 month period by the patients from the 381 families. The rate of physician visits for chronic disease was 2,375 per 1,000 population or slightly more than 2 visits per person per year. The rate of clinic visits was 1,517 per 1,000. This means a total amount of medical care for the chronic condition of approximately 4 visits per person per year. This same population group had an additional 2.5 visits per person for illness of a nonchronic nature. Chronic disease patients had from 3 to 4 times as much medical care for illness as did the other members of their families and the rest of the sample population studied.

Individuals in the 381 chronic disease families formed 26 per cent of the total observed population, had 54 per cent of the total illnesses, and received approximately 50 per cent of the medical care for illness given to the population. Individuals from these families also

constituted almost 40 per cent of the persons hospitalized during the second year of the morbidity study.*

DISCUSSION

From the data presented in this report it is evident that members of families selected on the basis of a case of chronic disease had an excess rate of illness compared with the remaining population. This was true for both chronic disease patients and for other members of the family. No attempt will be made to speculate as to the cause of this difference between groups of families. Some may be inclined to conclude that excess morbidity in these families suggests a concentration in certain families of individuals who through inheritance are less resistant to disease than the remainder of the population. A consideration of factors of the social environment, such as occupational class of the household head and the amount of medical care in relation to the amount of illness aside from chronic disease, revealed no striking differences between the two groups of families. However, there are other environmental factors which have not been a part of this study.

Sydenstricker, in a discussion of health and environment, said: "Diet, as determined by food supplies, dietary habits and economic status, is an important environmental factor in health."³ Diet is a factor which would not be expected to vary widely as to different members of the family unit. The morbidity study in the Eastern Health District of Baltimore, where the white population is homogeneous with respect to many environmental factors, should offer an unusual opportunity for the study of the relation of nutritional status to illness. Certainly, the influence of this factor upon morbidity must be carefully appraised before an excess of illness in certain family units can be considered

* Includes 21 institutional cases.

as proof of inheritance of a constitution of less vigor and vitality.

Louisiana Plans New Health Building

THE Louisiana State Board of Health, Baton Rouge, has approved plans for the construction of an office building for the State Board of Health, estimated to cost \$348,000. Included in the structure will be facilities for the central laboratories and office space for all the division and section heads. It is expected that the building will be occupied early in 1943.

New health centers have been approved for Alexandria and Shreveport, to cost about \$100,000. Smaller units have been approved for Leesville, DeRidder, Lake Charles and Lafayette, Crowley, Natchitoches, Winnfield, Marksville, Ville Platte, Glenmora, Lecompte, Colfax, Bunkie, Oakdale, Jena, Fillmore, Plain Dealing, and Elm Grove.

Use of the Index Case in the Study of Tuberculosis in Williamson County*

Statistician, Tennessee Department of Public Health; Professor of Hygiene and Public Health, Western Reserve University, Cleveland, Ohio; Director, Division of Tuberculosis Control; Director, Tuberculosis Study; and Commissioner, Tennessee Department of Public Health, Nashville, Tenn.

A SOUND program for the control of tuberculosis must be based on accurate knowledge of the prevalence of the disease and the risk of attack and of death for various classes of the population. To obtain such data for a rural area of Tennessee is one of the major objectives of the Williamson County Tuberculosis Study. Since household associates of cases constitute the most important of the classes at risk, the study program includes the investigation of the families of all cases of tuberculosis, the record of the family since establishment, the examination of the present members, and the continuous observation of these families.

The unit began work with the investigation of the reported cases known to the Williamson County Health Department and recorded deaths from the disease in the preceding 5 years. During the period of the study, the physicians of the county have been very coöperative and have referred known or sus-

pected cases to the clinic for examination. This has been the most productive method of discovery of cases and families for study. The data which are being collected and the methods of collection have been discussed in a previous report.¹

In the preliminary phases of the study, the problem of developing satisfactory methods for studying the prevalence of the disease and for calculating the risk of attack and of death for the household associates was recognized. It was noted that histories of tuberculosis among siblings, parents, grandparents, and other present or former members of the household were given frequently. Also the disease in the white population was often of an exceptionally chronic nature, sometimes causing no apparent disability. Unknown existing cases of this character were in fact found on examination of the present members. For these reasons the new case or death from tuberculosis which directed attention to the family was frequently found to be secondary to a case or cases of tuberculosis occurring in the past. The families with cases and deaths from the disease in the past without new recent cases were not followed. Therefore, the use of the secondary attack rate as used

* Read at a Joint Session of the Vital Statistics and Epidemiology Sections of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 16, 1941. From the Tennessee Department of Public Health. This investigation was made possible by the financial support of the International Health Division, Rockefeller Foundation.

in the study of acute diseases² was not believed to be satisfactory. A different method needed to be developed to eliminate such selection of the population and weighting of the group with secondary cases.

The work in the clinic was so organized that the individual who directed attention to the household was usually a case of tuberculosis or a recent death from the disease. Thus the inclusion of this person in the calculation of prevalence rates would necessarily reflect in high rates. To study the findings in families of various classes this case should be excluded so that the results of examination of associates could be compared.

For the calculation of attack and death rates over a period of time the late Dr. W. H. Frost had used a modified life table technic³ which has proved simple and flexible. However, it is recognized that death rates calculated from past records of families are unusually low. Deaths, especially those of infants, occurring in the past are often omitted. Also the life table experience of established families is known to exclude certain classes of adults who have high mortality rates. Another reason for the low mortality rates for families is the inclusion in the life experience of a living person who directed attention to the family. Naturally this individual cannot be assumed to have been at risk for death, since his survival was essential for the investigation of the family. Also the inclusion of the cases of tuberculosis who directed attention to the family in the life experience during the period of observation would increase the death rate, since persons suffering from the disease are at great risk for death.⁴

Dr. Frost, the consultant of the Tennessee Department of Public Health and Tuberculosis Studies, recognized the need for a relatively simple statistical procedure so that valid comparisons

could be made of the risks in different types of tuberculous families in Tennessee and elsewhere. To make such comparisons it is necessary to designate the person who directed attention to the family and then study the findings among his associates. By this method the defects inherent in the secondary attack rate and the inclusion of the informant can be eliminated. In the memorandum of his visit to Tennessee in June, 1933, Dr. Frost used the term "index case" in referring to the individual known or suspected to be suffering from tuberculosis. The proposed use of the index case is well described in a more extensive memorandum of Dr. Frost dated December 28, 1936, in which he expressed the practical questions with which the health officer is concerned in tuberculosis control:

"Given a case of tuberculosis of designated clinical type brought to the attention of the clinic because of known or suspected tuberculosis (not because of discovery in the course of examination of a known contact)—

"1. What may one expect to find in the household associates of this individual examined at this time with respect to: Frequency of infection as demonstrated by the tuberculin test; frequency of tuberculous lesions of various kinds as demonstrated by physical and x-ray examination?

"2. What may one expect to find in the antecedent history of this household with respect to the rate of occurrence of:

"Manifest tuberculosis,

"Death from tuberculosis,

"Death from other causes?

"3. What may one expect to find in subsequent years with respect to the rate of:

"Occurrence of manifest tuberculosis,

"Mortality from this cause and from other causes?"

Although the antecedent history has provided many interesting problems, this phase of the study has been dealt with rather extensively in a previous publication.¹ The present report will be concerned with (A) the prevalence of tuberculous infection and disease, and (B) the risk for associates during the period of observation.

A. PREVALENCE OF TUBERCULOUS INFECTION AND DISEASE AMONG ASSOCIATES OF INDEX CASES

In planning the local program of tuberculosis control, the health officer desires to use the most productive methods of case finding. He needs to know the value of examination of household associates of reported cases of tuberculosis. By studying the prevalence of infection and disease among associates of index cases the value of such examinations will be shown.

The results of examination of household associates in white and colored families at the time of investigation are given in Tables 1 and 2.

this report all data collected since the beginning of the study in December, 1931, and up to January 1, 1941, have been included. The household associates of white index cases totalled 2,094, of which 517 were associates of fatal and sputum-positive index cases, and 1,577 of other manifest and latent apical index cases. In the colored families there were 529 associates, of which 339 were associates of fatal and sputum-positive index cases, and 190 of the other group.

While 7.4 per cent of the household associates of fatal and sputum-positive index cases in white families were found to have manifest tuberculosis at the

TABLE 1

Results of Examinations of Associates in White and Colored Families at the Time of Investigation, According to the Character of Index Case

Results of Examination	White		Colored	
	Associates of Fatal and Sputum-Positive Index Cases	Associates of Other Manifest and Latent Apical Index Cases	Associates of Fatal and Sputum-Positive Index Cases	Associates of Other Manifest and Latent Apical Index Cases
Total	517	1,577	339	190
Manifest Tuberculosis	38	38	19	2
Latent Apical Tuberculosis	27	36	11	1
Latent Primary Tuberculosis	191	323	106	42
Negative	100	291	102	50
Not Examined	161	889	101	95

The associates have been studied according to the character of the index case—in two groups namely: (1) fatal and manifest sputum-positive, and (2) other manifest and latent apical. In

time of investigation, but 2.4 per cent of the associates of other manifest and latent apical cases were found to have manifest disease. In the colored families, 5.6 per cent of the associates in

TABLE 2

Percentage Frequency of Tuberculosis of Various Types Among Associates in White and Colored Families at the Time of Investigation According to the Character of Index Case

Results of Examination	White		Colored	
	Associates of Fatal and Sputum-Positive Index Cases	Associates of Other Manifest and Latent Apical Index Cases	Associates of Fatal and Sputum-Positive Index Cases	Associates of Other Manifest and Latent Apical Index Cases
Total	100.0	100.0	100.0	100.0
Manifest Tuberculosis *	7.4	2.4	5.6	1.1
Latent Apical Tuberculosis †	7.9	5.4	4.7	1.1
Latent Primary Tuberculosis †	55.7	48.5	45.7	44.7
Negative	29.0	43.7	44.0	53.1

* Percentages are proportions of associates with manifest tuberculosis multiplied by 100.

† Percentages are proportions of persons with latent lesions among those examined (excluding cases of manifest tuberculosis) applied to the percentage of population without manifest disease.

the first group and 1.1 per cent of those in the second group were found to have manifest tuberculosis.*

Therefore, in a tuberculosis control program emphasis should be given to the examination of household associates of a case known to have tubercle bacilli in the sputum or of a fatal case. The examination of contacts of tuberculosis in less severe stages is not as productive.

This study of the prevalence of tuberculosis among associates of index cases demonstrates the practical value of the use of the index case method to the health officer. The designation of the index case as the case which directed attention to the family is readily comprehended. Data on prevalence of the disease among household associates can be collected and analyzed by many workers.

B. THE RISK IN IMMEDIATE FUTURE TO HOUSEHOLD ASSOCIATES OF INDEX CASES

Many important administrative questions can be answered only when the expected future risk for household associates is known. It is necessary to know the approximate number of cases which may occur and when they will probably occur according to the various types of index cases.

With the use of the index case, the risk of attack has been measured in years subsequent to onset of the index case. To the present the published attack rates have included data from histories obtained at the time of first investigation of the household. However, considerable data have been collected for families under current observation in Williamson County.

The experience for associates in white families is shown in Table 3. In all, associates of fatal and sputum-positive index cases have been followed for 2,364.75 person-years and the associates of the other manifest and latent apical cases for 7,122.0 person-years. Eighteen new manifest cases have developed in the first group and 17 in the second group of associates. The case rate for the associates of fatal and sputum-positive index cases of 7.6 per 1,000 person-years was over three times the case rate of 2.4 per 1,000 person-years for associates of other manifest and latent apical cases.

Similar data are shown in Table 4 for the colored families. Among associates of colored fatal and sputum-positive index cases, 27 new manifest cases have developed, which gives the high attack rate of 20.5 per 1,000 person-years or a rate of 2 per cent per year.

TABLE 3

Cases, Deaths from Tuberculosis and Deaths from All Causes with Rates per 1,000 Person-years Among Associates in White Families During the Period of Observation According to the Character of Index Case

	Character of Index Case			
	Fatal and Sputum-Positive		Other Manifest and Latent Apical	
	Number	Rate	Number	Rate
Person-Years	2,364.75	7,122.0
Manifest Cases	18	7.6	17	2.4
Deaths from Tuberculosis	5	2.1	5	0.7
Deaths from All Causes	29	12.3	60	8.4

* In the present report a criterion for inclusion of associates has been added which was not used in previously published reports; that is, only associates are included who were known to have been in household association with the index case when the index case was known to have the disease.

This is approximately three times the case rate for colored associates of other manifest and latent apical index cases.

The tuberculosis death rate of 16.7

TABLE 4

Cases, Deaths from Tuberculosis and Deaths from All Causes with Rates per 1,000 Person-years Among Associates in Colored Families During the Period of Observation According to the Character of Index Case

	Character of Index Case			
	Fatal and Sputum-Positive		Other Manifest and Latent Apical	
	Number	Rate	Number	Rate
Person-Years	1,315.75	751.0 ^a
Manifest Cases	27	20.5	5	6.7
Deaths from Tuberculosis	22	16.7	2	2.7
Deaths from All Causes	44	33.4	11	14.6

per 1,000, or 1,670 per 100,000 person-years, is extremely high for these associates of the colored fatal and sputum-positive index cases. From these data it is evident that the risk of developing tuberculosis and the risk of dying from the disease is excessive in these colored families.

SUMMARY

The use of the index case method permits a valid comparison of the prevalence of the disease and the risk of attack and of death for household associates of cases of designated clinical

types of tuberculosis. From the knowledge obtained through the study of the disease by this method, a sound program can be developed for the control of tuberculosis.

Procurement and Assignment Service

THE Procurement and Assignment Service for Physicians, Dentists, and Veterinarians has started its machinery to secure 16,000 physicians and 3,000 dentists for the armed forces

before the end of 1942, without weakening the medical structure for civil and industrial populations as announced by Paul V. McNutt, Chairman of the War Manpower Commission.

The Connecticut State Department of Health Mental Hygiene Program^{*}

JAMES M. CUNNINGHAM, M.D.

*Director, Bureau of Mental Hygiene, State Department of Health,
Hartford, Conn.*

THE Connecticut State Department of Health began its work in the field of mental hygiene in February, 1920. The initial interest in a mental hygiene program in the department grew out of a conversation held in 1919 between Dr. John T. Black, then Commissioner of Health, and Dr. William B. Terhune, Medical Director of the Connecticut Society for Mental Hygiene. As a result of this conversation, a Division of Mental Hygiene was created in the Bureau of Preventable Diseases, and Dr. Terhune became the first chief of this Division on a part-time basis.

The work undertaken over the ensuing 21 years has varied in emphasis as well as in quantity. Three more or less distinct periods in the development of the program may be discerned.

The first period lies between 1920 and 1929. During this period there were several different psychiatrists who were part-time chiefs of the division. For short periods a psychologist was also employed part time, and there were similar short intervals in which there was a psychiatric social worker on the staff. During this time, the chief emphasis was on educational work. Hundreds of lectures on mental hygiene were given throughout the state, articles were written, and thousands of pamphlets distributed. Many surveys were

made of psychiatric facilities available, and of community needs. One of the most valuable pieces of work done, was a demonstration of the supervision of parole of state hospital patients by the use of psychiatric social workers. This was shortly taken over by the hospitals and has been maintained since as an integral part of the hospital function. During this period, there were two intervals when a psychologist was employed part time to give mental tests to some 689 children in the county homes.

The second period in the development of the mental hygiene program falls between 1929 and 1935. In 1929, sufficient funds were secured for a full-time chief of the division and for two psychiatric social workers. In 1931, the division was raised to the status of a bureau in the department by legislative enactment. The services of the social workers, or mental hygienists as they are classified in Connecticut, were not maintained throughout the entire period because of reduction in budget as a result of the depression in 1933.

Great emphasis was placed on the educational program, and a large number of lectures were given throughout the state. There were numerous articles and radio talks. Many new pamphlets were bought or prepared and widely distributed. A program of psychiatric clinics for children was inaugurated. These were held in various towns by arrangement, but this type of schedule of clinics did not permit routine fol-

^{*} Read before the Health Officers Section of the American Public Health Association at the Seventieth Annual Meeting in Atlantic City, N. J., October 14, 1941.

low-up treatment of cases. As a result, these clinics were largely diagnostic. Children were examined, and recommendations left with responsible people in the various communities. Six hundred and nineteen cases were examined during this period.

The third period in the development of the department's mental hygiene program lies between 1935 and the present date. The 1935 general assembly restored the former budget, and in 1936 Social Security Funds became available to augment the staff of the bureau. The major activities during the past 6 years have been: (1) the clinical program, (2) the educational program, (3) participation in the activities of various community organizations, (4) licensure and inspection of the private nervous and mental hospitals, (5) activities in connection with war emergency. These functions will be described individually.

The clinical work of the bureau is by far its major activity. All of the time of the professional staff goes into this work except that of the director, who gives some clinical service. The professional staff at this time consists of 2 psychiatrists, 1 psychologist, and 4 mental hygienists. Funds have been recently appropriated for an additional psychologist.

The clinical program conducted at the present time is an active psychiatric treatment program for children. It was felt that adult clinics were less close to the field of prevention than clinics for children. It was also believed that better results could be obtained with children in terms of the money available, and that a psychiatric program for adults would be better if it were developed in connection with the general hospital and dispensary. An active treatment program for children was instituted because diagnostic clinics had been tried with not too encouraging results. People in the various communities were as a rule not capable of carry-

ing out recommendations left with them after diagnoses had been made. Furthermore, initial enthusiasm for mental hygiene work became stifled upon the realization that the disturbing behavior of the children referred had to be dealt with in spite of attached diagnostic labels.

Psychiatric work with children had developed over a period of years. Under the leadership of the Commonwealth Fund and the National Committee for Mental Hygiene, a practical clinical organization and methods of work had evolved. Such psychiatric clinics for children were, for the most part, known as child guidance clinics. The chief characteristic of these clinics was the utilization of three specialized professions in an integrated attack upon the various behavior and personality problems of children.

The problem of developing such a clinical service in the Bureau of Mental Hygiene resolved itself into one of the distribution of this combined technical service to smaller units of population than could afford or utilize these services on a full-time basis. It is impossible for the smaller communities to secure properly qualified psychiatrists, psychologists, and psychiatric social workers in the proper ratio to one another and for the limited amount of time for which the population has need. Attempts have been made to use one or another of these types of professions to do the whole job. While each can do certain work independently, the chief advantage of the child guidance clinic is lost, namely, the integration of all of these into a clinical attack upon the problem. The use of unqualified or poorly qualified personnel is more wasteful than in almost any other type of work.

The experience of the National Committee for Mental Hygiene had been that a clinical unit could be locally supported and utilized to full capacity

in communities with populations between 200,000 and 300,000. Experience in clinical work with children had shown that 90 to 95 per cent of all children coming to the child guidance clinic could be treated if they could return as often as once a week for treatment interviews, and a considerable proportion of the children required less frequent visits.
